Timing for priority (PIFS, DIFS), contention backoff (slot times), and CS/CCA windows is defined relative to the end of the last bit of the last packet on the air. The CS/CCA state machine is shown in Figure 14-9. The PLCP shall perform a CS/CCA on a minimum of one antenna within a MAC contention backoff slot time of 50 µs. The PLCP shall be capable of detecting within the slot time an FH-PHY-conformant signal that is received at the selected antenna up to 22 µs after the start of the slot time with the synchronous detection performance specified in 14.7.15.4. Detection performance with 01 sync patterns and with random data patterns is specified in 14.7.15.4. If a start of a transmission is asynchronous with the BSS and arrives after the start of the slot but at least 16 µs prior to the end of the slot, the PLCP shall indicate a busy channel prior to the end of the slot time with the asynchronous detection performance specified in 14.7.15.4. The CCA indication immediately prior to transmission shall be performed on an antenna with essentially the same free space gain and gain pattern as the antenna to be used for transmission. The method of determining CS/CCA is unspecified except for the detection performance of a conformant method as specified in 14.7.15.4.

If a PHY-TXSTART.request(TXVECTOR) primitive is received, the CS/CCA procedure shall exit to the transmit procedure within 1 µs. If a PHY-CCARESET.request primitive is received, the PLCP shall reset the CS/CCA state machine to the state appropriate for the end of a complete received frame. This service primitive is generated by the MAC at the end of a NAV period. The PHY shall indicate completion of the request by sending a PHY-CCARESET.confirm primitive to the MAC.

If a CS/CCA returns a channel idle result, the PHY shall send a PHY-CCA.indication(STATUS=idle) primitive to the MAC.
If a CS/CCA returns a channel busy result, the PHY shall send a PHY-CCA.indication(STATUS=busy) primitive to the MAC. Upon a channel busy assessment, the PLCP shall stop any antenna switching prior to the earliest possible arrival time of the SFD and detect a valid SFD and PLCP header if received. A valid PLCP header is defined as containing valid PLW and PSF values and a valid HEC field. If a valid SFD/PLCP header is detected, the CS/CCA procedure shall send a PHY-RXSTART.indication(RXVECTOR) primitive to the MAC sublayer and exit to the receive procedure. The PLCP shall dwell and search for the SFD/PLCP header for a minimum period longer than the latest possible arrival time of the SFD/PLCP header. Indication of a busy channel does not necessarily lead to the successful reception of a frame. The octet/bit count remaining may be a nonzero value when returning from the receive procedure if a signal in the process of being received was lost prior to the end as determined from the LENGTH field of a valid PLCP header. The countdown timer shall be set to the octet/bit count and used to force the CS/CCA indication to remain in the BUSY state until the predicted end of the frame regardless of actual CS/CCA indications.

However, if the CS/CCA procedure indicates the start of a new frame within the countdown timer period, it is possible to transition to the receive procedure prior to the end of the countdown timer period. If the PHY transitions to receive under these conditions, the countdown timer shall be reset to the longer of

— The remaining time of the current frame or
— The length of the new frame.

Figure 14-9—CS/CCA state machine
When a nonzero countdown timer reaches 0, the PLCP shall reset the CS/CCA state machine to the state appropriate for the end of a complete received frame and the CS/CCA indication shall reflect the state of the channel.

If the receive procedure encountered an unsupported rate error, the PLCP shall keep the CS/CCA state at Busy for the duration of the frame by setting the countdown timer to the value corresponding to the calculated time based on the information in the PLCP header and the 33/32 expansion factor.

### 14.4.4.3.3 CS/CCA state timing

Timing for priority (PIFS, DIFS), contention backoff (slot times), and CS/CCA windows is defined relative to the end of the last bit of the last packet on the air. The PLCP shall perform a CS/CCA on a minimum of one antenna within a slot time. The appropriate CS/CCA indication shall be available prior to the end of each 50 µs slot time with the performance specified in 14.7. See Figure 14-10.

If a STA has not successfully received the previous packet, the perceived packet end time and slot boundary times have a higher uncertainty for that STA.

### 14.4.4 Receive PLCP

#### 14.4.4.1 General

The receive PLCP is invoked by the CS/CCA procedure upon detecting a portion of the preamble sync pattern followed by a valid SFD and PLCP header.

#### 14.4.4.2 Receive state machine

The receive PLCP shown in Figure 14-11 includes functions that need to be performed while the PPDU is being received. The receive PLCP begins upon detection of a valid SFD and PLCP header in the CS/CCA procedure. The PLCP shall set a PPDU octet/bit counter to indicate the last bit of the packet, receive the PPDU bits, and perform the data whitening decoding procedure shown in Figure 14-12 on each PPDU bit. The PLCP shall pass correctly received data octets to the MAC with a series of PHY-DATA.indication(DATA) primitives. After the last PPDU bit is received and the last octet is passed to the MAC, the PLCP shall send a PHY-RXEND.indication(RXERROR=no_error) primitive to the MAC sublayer. Upon error-free completion of a packet reception, the PLCP shall exit the receive procedure and return to the CS/CCA procedure with the octet/bit count set to 0.

If the PLCP header was decoded without a CRC error but encountered an unsupported rate, then the PLCP shall immediately complete the receive procedure with a PHY-RXEND.indication(RXERROR = unsupported_rate) primitive to the MAC, and return to the CS/CCA procedure with the octet/bit count remaining and the data rate value contained in the PLCP header.

If an error was detected during the reception of the PPDU, the PLCP shall immediately complete the receive procedure with a PHY-RXEND.indication(RXERROR=carrier_lost) primitive to the MAC, and return to the CS/CCA procedure with the octet/bit count remaining and the data rate value contained in the PLCP header.

```c
/*  If MSB of stuff symbol = 1 then the next block is inverted; 0 = not inverted */
/* Stuffing begins on first symbol of PLCP header following the SFD */
/* Algorithm begins after verifying validity of header with HEC */

/********* Read header ***********/
Read in header {b(1),...,b(32)}; /* b(1) is first bit in */

Get number_of_PSDU_octets, rate from header; /* rate is 1 or 2 */
number_of_symbols = (number_of_PSDU_octets*8)/rate
number_of_blocks_in_packet = truncate{(number_of_symbols + 31) / 32};
Initialize scrambler to all ones;

/********* Dewhiten the PPDU data with BSE decoder and descrambler ***********/
For n = 1 to number_of_blocks_in_packet {
    N = min(32, # of symbols remaining); /* N= block size in symbols */
    Read in next block {b(0),...,b(N)}; /* b(n) = {0,1} or {0,1,2,3} */
    If {MSB of b(0)=1} then Invert {b(1),...,b(N)}; /* if invert bit=true */
    Descramble {b(1),...,b(N)}; /* see 14.4.3.4 */
    Send {b(1),...,b(N)} to MAC /* 1 - 8 octets; use PHY-DATA.indication(DATA) for each octet */
}
```

Figure 14-12—Data whitener decoding procedure
14.4.4.4.3 Receive state timing

The receive state timing shown in Figure 14-13 is defined to begin upon detection of a valid SFD and PLCP header in the CS/CCA procedure. The PLCP shall begin receiving the variable-length whitened PSDU immediately after the end of the last bit of the PLCP header. The PLCP shall send a PHY-RXEND.indication(RXERROR) primitive after receiving the last PPDU data bit.

If any error was detected during the reception of the PPDU, the PLCP may send a PHY-RXEND.indication(RXERROR) primitive and terminate the receive procedure before the last bit arrives.

14.5 PLME SAP layer management

14.5.1 Overview

Subclause 14.5 describes the services provided by the FHSS PLME to the upper LMEs. The PLME/PMD services are defined in terms of service primitives. These primitives are abstract representations of the services and are not intended to restrict implementations.

14.5.2 FH PHY specific MLME procedures

14.5.2.1 Overview

The specific MLME procedures required for operating the FHSS PHY are specified in this portion of the subclause. The relationship between the MLME and FH PLME procedures is also described.

14.5.2.2 FH synchronization

The MLME of a compliant FH PHY STA shall perform the FH time synchronization procedure as defined in 10.1.6. This procedure provides for synchronized FH for all compliant FH PHY STAs within a single BSS. The FH PLME accepts PLME-SET.request primitives from the MLME to change the tune frequency at the time determined by the MLME. The tune frequency is changed by updating any combination of the Set, Pattern, and Index PHY MIB parameters.

14.5.3 FH PLME state machines

14.5.3.1 Overview

Subclause 14.5.3 describes the FH PLME state machines to turn the PMD on/off, reset the PLCP state machine, and change the frequency hop channel.

14.5.3.2 PLME state machine

The PLME state machine in Figure 14-14 begins with a PLME-SET.request(dot11CurrentPowerState= ON) primitive, which turns on the PHY circuitry, resets the PLME and PLCP state machines, and sends a PLME-SET.confirm primitive. The MAC then sends a series of three PLME-SET.request primitives to update the dot11CurrentSet, dot11CurrentPattern, and dot11CurrentIndex PHY MIB parameters, which together tune the PMD to the selected channel. The PLME then transfers execution to the PLCP state machine as defined in 14.4.4.
Upon receiving a PLME request from a higher level management entity, the PLCP shall return execution to the PLME state machine and process the request. A PLME-RESET.request primitive shall cause a reset to the PLME and PLCP state machines. A PLME-SET.request primitive updating the dot11CurrentIndex or a combination of the dot11CurrentSet, dot11CurrentPattern, and dot11CurrentIndex shall cause the PLCP to terminate a receive or CS/CCA process and change frequency before returning to the PLCP state machine. A PLME-SET.request(dot11CurrentPowerState=OFF) primitive shall cause the PLCP to terminate a receive or CS/CCA process, power-down the PMD circuitry, and return the PLME state machine to the idle state. PLME-SET.request primitives to any parameter other than the ones identified within this paragraph shall be executed and control shall be returned to the PLCP state machine. The MAC should not send a PLME request while the PLCP is in the transmit state.

All PLME-GET.request primitives shall be processed in parallel and with no interruption to the execution of any state machine in process.

14.5.3.3 PLME management primitives

The FH PLME uses the generic management primitives defined in 6.2 to manage all FH PHY parameters.
14.6 FHSS PMD sublayer services

14.6.1 Scope and field of application

The PMD services provided to the PLCP for the FHSS PHY are described in 14.6. Also defined in 14.6 are the functional, electrical, and radio frequency (RF) characteristics required for interoperability of implementations conforming to this specification. The relationship of this specification to the entire FHSS PHY is shown in Figure 14-15.

![Figure 14-15—PMD layer reference model](image)

14.6.2 Overview of services

In general, the FHSS PMD sublayer accepts PLCP sublayer service primitives and provides the actual means by which the signals required by these primitives are imposed onto the medium. In the FHSS PMD sublayer at the receiver the process is reversed. The combined function of the transmitting and receiving FHSS PMD sublayers results in a data stream, timing information, and receive parameter information being delivered to the receiving PLCP sublayer.

14.6.3 Overview of interactions

The primitives associated with the IEEE 802.11 PLCP sublayer to the FHSS PMD sublayer fall into the following two basic categories:
   a) Service primitives that support PLCP peer-to-peer interactions;
   b) Service primitives that have local significance and support sublayer-to-sublayer interactions.

14.6.4 Basic service and options

14.6.4.1 General

All of the service primitives described in 14.6.4 are considered mandatory unless otherwise specified.

14.6.4.2 PMD_SAP peer-to-peer service primitives

Table 14-5 indicates the primitives for peer-to-peer interactions.

14.6.5 PMD_SAP detailed service specification

14.6.5.1 Introduction

Subclause 14.6.5 describes the services provided by each PMD primitive.

14.6.5.2 PMD_DATA.request

14.6.5.2.1 Function

This primitive defines the transfer of data from the PLCP sublayer to the PMD entity.
14.6.5.2.2 Semantics of the service primitive

The primitive shall provide the following parameter:

\[ \text{PMD\_DATA.request(TXD\_UNIT)} \]

The TXD\_UNIT parameter takes on one of two values: 1 or 0. This parameter represents a single data bit. The effect of this parameter is that the PMD properly modulates the medium to represent 1s or 0s as defined in the FHSS PMD modulation specifications for a given data rate.

14.6.5.2.3 When generated

This primitive is generated by the PLCP sublayer to request the transmission of a single data bit on the PMD sublayer. The bit clock is assumed to be resident or part of the PLCP and this primitive is issued at every clock edge once the PLCP has begun transmitting data.

14.6.5.2.4 Effect of receipt

The receipt of this primitive causes the PMD entity to encode and transmit a single data bit.

14.6.5.3 PMD\_DATA.indication

14.6.5.3.1 Function

This primitive defines the transfer of data from the PMD entity to the PLCP sublayer.

14.6.5.3.2 Semantics of the service primitive

The primitive shall provide the following parameter:

\[ \text{PMD\_DATA.indication(RXD\_UNIT)} \]

The RXD\_UNIT parameter takes on one of two values: 1 or 0. This parameter represents the current state of the medium as determined by the FHSS PMD modulation specifications for a given data rate.

14.6.5.3.3 When generated

The PMD\_DATA.indication is generated to all receiving PLCP entities in the network after a PMD\_DATA.request primitive is issued.

14.6.5.3.4 Effect of receipt

The effect of receipt of this primitive by the PLCP is unspecified in this standard.

14.6.5.4 PMD\_TXRX.request

14.6.5.4.1 Function

This primitive is used to place the PMD entity into the transmit or receive function.

14.6.5.4.2 Semantics of the service primitive

The primitive shall provide the following parameter:

\[ \text{PMD\_TXRX.request(RF\_STATE)} \]
The RF_STATE parameter takes on one of two values: TRANSMIT or RECEIVE. When the value of the primitive is TRANSMIT, the RF state of the radio is transmit. If the value of the primitive is RECEIVE, the RF state of the radio is receive.

14.6.5.4.3 When generated

This primitive is generated when the mode of the radio needs to be set or when changing from transmit to receive or receive to transmit.

14.6.5.4.4 Effect of receipt

The receipt of this primitive by the PMD entity causes the mode of the radio to be in either transmit or receive.

14.6.5.5 PMD_PA_RAMP.request

14.6.5.5.1 Function

This primitive defines the start of the ramp up or ramp down of the radio transmitter’s power amplifier.

14.6.5.5.2 Semantics of the service primitive

The primitive shall provide the following parameter:

   PMD_PA_RAMP.request(RAMP_STATE)

The RAMP_STATE parameter takes on one of two values: ON or OFF. When the value of the primitive is ON, the state of the transmit power amplifier is “on.” If the value of the primitive is OFF, the state of the transmit power amplifier is “off.”

14.6.5.5.3 When generated

This primitive is issued only during transmit and to establish the initial state. It is generated by the PLCP at the start of the transmit function to turn the transmitter’s power amplifier “on.” A power amplifier ramp-up period follows the change of state from “off” to “on.” After the PLCP has transferred all required data to the PMD entity, this primitive is again issued by the PLCP to place the transmit power amplifier back into the “off” state. A power amplifier ramp-down period follows the change of state from “on” to “off.”

14.6.5.5.4 Effect of receipt

The receipt of this primitive by the PMD entity causes the transmit power amplifier to turn on or off.

14.6.5.6 PMD_ANTSEL.request

14.6.5.6.1 Function

This primitive is used to select which antenna the PMD entity uses to transmit or receive data.

14.6.5.6.2 Semantics of the service primitive

The primitive shall provide the following parameter:

   PMD_ANTSEL.request(ANTENNA_STATE)

The ANTENNA_STATE parameter takes on values from one to \( N \) (where \( N \) is the number of antennas supported). When the value of the primitive is a ONE, the PMD switches to antenna 1 for receive or
transmit; if the value of the primitive is TWO, the PMD entity switches to antenna 2 for receive or transmit, etc.

14.6.5.6.3 When generated

This primitive is generated at various times by the PLCP entity to select an antenna. During receive, this primitive can be used to manage antenna diversity. During transmit, this primitive can be used to select a transmit antenna. This primitive is also used during CCA.

14.6.5.6.4 Effect of receipt

The receipt of this primitive by the PMD entity causes the radio to select the antenna specified.

14.6.5.7 PMD_TXPWRLEVEL.request

14.6.5.7.1 Function

This primitive defines the power level the PMD entity uses to transmit data.

14.6.5.7.2 Semantics of the service primitive

The primitive shall provide the following parameter:

\[
\text{PMD\_TXPWRLEVEL\_request}(\text{TXPOWER\_LEVEL})
\]

The TXPOWER\_LEVEL parameter can be one of the values listed in Table 14-8.

<table>
<thead>
<tr>
<th>TXPWR_LEVEL</th>

</tr>
<tr>
<td>LEVEL8</td>
<td>Defined as TxPowerLevel8 in MIB</td>
</tr>
</tbody>
</table>

14.6.5.7.3 When generated

This primitive is generated as part of the transmit sequence.

14.6.5.7.4 Effect of receipt

The receipt of this primitive by the PMD entity causes the transmit power level to be modified.
14.6.5.8 PMD_FREQ.request

14.6.5.8.1 Function

This primitive defines the frequency the PMD entity uses to receive or transmit data. Because changing the RF is not an immediate function, this primitive serves also as an indication of the start of this process. The completion of this process is dictated by other PMD specifications.

14.6.5.8.2 Semantics of the service primitive

The primitive shall provide the following parameter:

\[ \text{PMD}_\text{_FREQ}.\text{request} (\text{CHANNEL\_ID}) \]

The CHANNEL_ID parameter can be one of the values listed in Table 14-11, Table 14-12, Table 14-13, or Table 14-14 (in 14.7.5).

14.6.5.8.3 When generated

This primitive is generated by the PLCP when a change to a new frequency is required.

14.6.5.8.4 Effect of receipt

The receipt of this primitive by the PMD entity causes the radio to change to a new frequency defined by the value of the CHNL_ID.

14.6.5.9 PMD_RSSI.indication

14.6.5.9.1 Function

This primitive transfers a receiver signal strength indication of the physical medium from the PMD sublayer to the PLCP sublayer. This value is used by the PLCP to perform any diversity or CCA functions required by the PLCP or other sublayers.

14.6.5.9.2 Semantics of the service primitive

The primitive shall provide the following parameter:

\[ \text{PMD}_\text{_RSSI}.\text{indication} (\text{STRENGTH}) \]

The STRENGTH parameter can be a value from 0 to 15. This parameter is an indication by the PMD sublayer of the magnitude of the energy observed at the selected antenna. This reported value is used to generate the RSSI term in the PHY-RXSTART.indication(RXVECTOR) primitive and might also be used by any diversity function. Because RSSI is only used in a relative manner by the MAC sublayer, this parameter is defined to have no more than 16 values, ranging from 0 to RSSI_Max. The value 0 is the weakest signal strength, while RSSI_Max is the strongest signal strength.

14.6.5.9.3 When generated

This primitive is generated continually by the PMD entity to transfer a RSSI to the PLCP.

14.6.5.9.4 Effect of receipt

The effect of receipt of this primitive by the PLCP is unspecified in this standard.
14.6.5.10 PMD_PWRMGMT.request

14.6.5.10.1 Function

This primitive is used by the higher layer entities to manage or control the power consumption of the PMD when not in use. This allows higher layer entities to put the radio into a sleep or standby mode when receipt or sending of any data is not expected.

14.6.5.10.2 Semantics of the service primitive

The primitive shall provide the following parameter:

\[ \text{PMD_PWRMGMT.request(MODE)} \]

The MODE parameter takes one of two values: ON or OFF. When the value of the parameter is ON, the PMD entity enters into a fully functional mode that allows it to send or receive data. When the value of the parameter is OFF, the PMD entity places itself in a standby or power-saving mode. In the low-power mode, the PMD entity is not expected to be able to perform any request by the PLCP, nor is it expected to indicate any change in PMD state or status.

14.6.5.10.3 When generated

This primitive is delivered by the PLCP but actually is generated by a higher level LME.

14.6.5.10.4 Effect of receipt

Upon receipt of this primitive, the PMD entity enters a fully functional or low power consumption state depending on the value of the primitive’s parameter.

14.7 FHSS PMD sublayer, 1.0 Mb/s

14.7.1 1 Mb/s PMD operating specifications, general

In general, the PMD accepts convergence layer service primitives and provides the actual means by which the signals required by these primitives are imposed on the medium. In the PMD sublayer at the receiver, the process is reversed. The combined function of the transmitting and receiving PMD sublayers results in a data stream, timing information, and receive parameter information being delivered to the receiving convergence sublayer.

14.7.2 Regulatory requirements

WLANs implemented in accordance with this standard are subject to equipment certification and operating requirements established by regional and national regulatory administrations. The PMD specification establishes minimum technical requirements for interoperability, based upon established regulations at the time this standard was issued. These regulations are subject to revision, or may be superseded. Requirements that are subject to local geographic regulations are annotated within the PMD specification. Regulatory requirements that do not affect interoperability are not addressed within this standard. Implementers are referred to the appropriate regulatory sources for further information. Table 14-9 specify the current regulatory requirements for various geographic areas at the time this standard was developed. They are provided for information only and are subject to change or revision at any time.
14.7.3 Operating frequency range

A conformant PMD implementation shall be able to select the carrier frequency \((F_c)\) from the full geographic-specific set of available carrier frequencies. Table 14-9 summarizes these frequencies for a number of geographic locations.

### Table 14-9—Operating frequency range

### 14.7.4 Number of operating channels

The number of transmit and receive frequency channels used for operating the PMD entity is 79 for the United States and Europe, and 23 for Japan. Table 14-10 summarizes these frequencies for a number of geographic locations. This is more fully defined in Table 14-11 to Table 14-14.

### 14.7.5 Operating channel center frequency

The channel center frequency is defined in sequential 1.0 MHz steps beginning with the first channel, channel 2.402 GHz for China, the United States, and Europe excluding Spain and France, as listed in Table 14-11. The channel centers for Japan, starting at 2.473 GHz with 1 MHz increments, are listed in Table 14-12. The channel centers for Spain and France are listed in Table 14-13 and Table 14-14, respectively.

14.7.6 Occupied channel bandwidth

Occupied channel bandwidth shall meet all applicable local geographic regulations for 1 MHz channel spacing. The rate at which the PMD entity hops is governed by the MAC. The hop rate is an attribute with a maximum dwell time subject to local geographic regulations.

14.7.7 Minimum hop rate

The minimum hop rate shall be governed by the regulatory authorities.

14.7.8 Hop sequences

The hopping sequence of an individual PMD entity is used to create a pseudorandom hopping pattern utilizing uniformly the designated frequency band. Sets of hopping sequences are used to collocate multiple PMD entities in similar networks in the same geographic area and to enhance the overall efficiency and throughput capacity of each individual network.

An FH pattern, $F_x$, consists of a permutation of all frequency channels defined in Table 14-11 and Table 14-12. For a given pattern number, $x$, the hopping sequence is given by the following:

$$F_x = \{f_x(1), f_x(2), \ldots f_x(p)\}$$  \hspace{1cm} (14-1)

where

- $f_x(i)$ is the channel number (as defined in 14.7.4) for $i^{\text{th}}$ frequency in $x^{\text{th}}$ hopping pattern;
- $p$ is the number of frequency channels in hopping pattern (79 for China, North America and most of Europe, 23 for Japan, 35 for France, 27 for Spain).

Given the hopping pattern number, $x$, and the index for the next frequency, $i$ (in the range 1 to $p$), the channel number shall be defined to be as follows:

- $f_x(i) = [b(i) + x] \mod 79 + 2$ in China, North America and most of Europe, with $b(i)$ defined in Table 14-15.
- $f_x(i) = [(i - 1) \times x] \mod 23 + 73$ in Japan.
- $f_x(i) = [b(i) + x] \mod 27 + 47$ in Spain with $b(i)$ defined in Table 14-16.
- $f_x(i) = [b(i) + x] \mod 35 + 48$ in France with $b(i)$ defined in Table 14-17.

The sequences are designed to ensure some minimum distance in frequency between contiguous hops. The minimum hop size is 6 MHz for China, North America and Europe, including Spain and France, and 5 MHz for Japan.

</table>
The hopping pattern numbers $x$ are divided into three sets. The sets are designed to avoid prolonged collision periods between different hopping sequences in a set. Hopping sequence sets contain 26 sequences for China, North America and Europe, and 4 sequences per set for Japan:

For China, North America and most of Europe:
- $x = \{0,3,6,9,12,15,18,21,24,27,30,33,36,39,42,45,48,51,54,57,60,63,66,69,72,75\}$ Set 1
- $x = \{1,4,7,10,13,16,19,22,25,28,31,34,37,40,43,46,49,52,55,58,61,64,67,70,73,76\}$ Set 2
- $x = \{2,5,8,11,14,17,20,23,26,29,32,35,38,41,44,47,50,53,56,59,62,65,68,71,74,77\}$ Set 3

For Japan:
- $x = \{6,9,12,15\}$ Set 1
- $x = \{7,10,13,16\}$ Set 2
- $x = \{8,11,14,17\}$ Set 3

For Spain:
- $x = \{0,3,6,9,12,15,18,21,24\}$ Set 1
- $x = \{1,4,7,10,13,16,19,22,25\}$ Set 2
- $x = \{2,5,8,11,14,17,20,23,26\}$ Set 3

For France:
- $x = \{0,3,6,9,12,15,18,21,24,27,30\}$ Set 1
- $x = \{1,4,7,10,13,16,19,22,25,28,31\}$ Set 2
- $x = \{2,5,8,11,14,17,20,23,26,29,32\}$ Set 3

The three sets of hopping sequences for China, North America and most of Europe, of 26 patterns each, are listed in Table I-1, Table I-2, and Table I-3. Similarly, there are three sets for Japan of four patterns each. The three sets for Spain have nine patterns each. The three sets for France have 11 patterns each. The channel numbers listed under each pattern refer to the actual frequency values listed in Table 14-11 and Table 14-12.

### 14.7.9 Unwanted emissions

Conformant PMD implementations shall limit the emissions that fall outside of the operating frequency range, defined in Table 14-9, to the geographically applicable limits.

### 14.7.10 Modulation

The minimum set of requirements for a PMD to be compliant with the IEEE 802.11 FHSS PHY shall be as follows.
The PMD shall be capable of operating using 2GFSK modulation with a nominal bandwidth bit time (BT) = 0.5. The PMD shall accept symbols from the set \{\{1\},\{0\}\} from the PLCP. The symbol \{1\} shall be encoded with a peak deviation of \((+f_d)\), giving a peak transmit frequency of \((F_c+f_d)\), which is greater than the carrier center frequency \((F_c)\). The symbol \{0\} shall be encoded with a peak frequency deviation of \((-f_d)\), giving a peak transmit frequency of \((F_c-f_d)\).

An incoming bit stream at 1 Mb/s shall be converted to symbols at \(F_{clk} = 1\) Msymbols/s, as shown in Table 14-18.

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Carrier deviation</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>(1/2 \times h2 \times F_{clk})</td>
</tr>
<tr>
<td>0</td>
<td>(-1/2 \times h2 \times F_{clk})</td>
</tr>
</tbody>
</table>

NOTE—These deviation values are measured using the center symbol of 7 consecutive symbols of the same value. The instantaneous deviation will vary due to Gaussian pulse shaping.

The deviation factor \(h2\) for 2GFSK (measured as difference between frequencies measured in the middle of 0000 and 1111 patterns encountered in the SFD, divided by 1 MHz) is nominally 0.32.

The minimum frequency deviation, as shown in Figure 14-16, shall be greater than 110 kHz relative to the nominal center frequency \(F_c\). \(F_d\) is the average center frequency of the last 8 bits of the Preamble SYNC field, measured as the deviation at the midsymbol. Midsymbol is defined as the point that is midway between the zero crossings derived from a best fit to the last 8 bits of the Sync field. Maximum deviation is not specified, but modulation is subject to the occupied bandwidth limits of 14.7.5.

The zero crossing error shall be less than \(\pm 1/8\) of a symbol period. The zero crossing error is the time difference between the ideal symbol periods and measured crossings of \(F_c\). This is illustrated in Figure 14-16.
14.7.11 Channel data rate

A compliant IEEE 802.11 FHSS PMD shall be capable of transmitting and receiving at a nominal data rate of 1.0 Mb/s ±50 ppm.

14.7.12 Channel switching/settling time

The time to change from one operating channel frequency, as specified in 14.7.3, is defined as 224 µs. A conformant PMD meets this switching time specification when the operating channel center frequency has settled to within ±60 kHz of the nominal channel center frequency as outlined in 14.7.3.

14.7.13 Receive to transmit switch time

The maximum time for a conformant PMD to switch the radio from the receive state to the transmit state and place the start of the first bit on the air shall be 19 µs. At the end of this 19 µs, the RF carrier shall be within the nominal transmit power level range, and within the described modulation specifications.

14.7.14 PMD transmit specifications

14.7.14.1 Introduction

Subclause 14.7.14 describes the transmit functions and parameters associated with the PMD sublayer. In general, these are specified by primitives from the PLCP, and the transmit PMD entity provides the actual means by which the signals required by the PLCP primitives are imposed onto the medium.

14.7.14.2 Nominal transmit power

The nominal transmit power of a frame is defined as the power averaged between the start of the first symbol in the PLCP header to the end of the last symbol in the PLCP header. When in the transmit state, the transmit power shall be within 2 dB of the nominal transmit power from the start of the Preamble SYNC field to the last symbol at the end of the frame.

14.7.14.3 Transmit power levels

Unless governed by more stringent local geographic regulations, the radiated emissions from compliant devices shall meet IEEE Std C95.1 limits for controlled or uncontrolled environments, in accordance with their intended usage. In addition, all conformant PMD implementations shall support at least one power level with a minimum equivalent isotropically radiated power (EIRP) of 10 mW.

14.7.14.4 Transmit power level control

If a conformant PMD implementation has the ability to transmit in a manner that results in the EIRP of the transmit signal exceeding the level of 100 mW, at least one level of TPC shall be implemented. This TPC shall be such that the level of the emission is reduced to a level at or below 100 mW under the influence of said power control.

14.7.14.5 Transmit spectrum shape

Within the operational frequency band the transmitter shall pass a spectrum mask test. The duty cycle between Tx and Rx is nominally 50% and the transmit frame length is nominally 400 µs. The adjacent channel power is defined as the sum of the power measured in a 1 MHz band. For a pseudorandom data pattern, the adjacent channel power shall be a function of the offset between channel number $N$ and the assigned transmitter channel $M$, where $M$ is the actual transmitted center frequency and $N$ is a channel separated from it by an integer number of megahertz.
Channel offset:
\[ |N - M| = 2 \quad -20 \text{ dBm or } -40 \text{ dBC}, \text{ whichever is the lower power.} \]
\[ |N - M| \geq 3 \quad -40 \text{ dBm or } -60 \text{ dBC}, \text{ whichever is the lower power.} \]

The levels given in dBC are measured relative to the transmitter power measured in a 1 MHz channel centered on the transmitter center frequency. The adjacent channel power and the transmitter power for this subclause of the specification shall be measured with a resolution bandwidth of 100 kHz, a video bandwidth of 300 kHz, and a peak detector, and with the measurement device set to maximum hold.

For any transmit center frequency M, two exceptions to the spectrum mask requirements are permitted within the operational frequency band, provided the exceptions are less than –50 dBC, where each offset channel exceeded counts as a separate exception. An exception occurs when the total energy within a given 1 MHz channel as defined in 14.7.5 exceeds the levels specified in 14.7.14.2 to 14.7.14.5.

**14.7.14.6 Transmit center frequency tolerance**

The PMD transmit center frequency shall be within ±60 kHz of the nominal center frequency as specified in 14.7.5.

**14.7.14.7 Transmitter ramp periods**

The transmitter shall go from off to within 2 dB of the nominal transmit power in 8 µs or less. The transmitter shall go from within 2 dB of the nominal transmit power to off (less than –50 dBm) in 8 µs or less.

**14.7.15 PMD receiver specifications**

**14.7.15.1 Introduction**

Subclause 14.7.15 describes the receive functions and parameters associated with the PMD sublayer. In general, these are specified by primitives from the PLCP. The Receive PMD entity provides the actual means by which the signals required by the PLCP primitives are recovered from the medium. The PMD sublayer monitors signals on the medium and returns symbols from the set \{\{1\},\{0\}\} to the PLCP sublayer.

**14.7.15.2 Input signal range**

The PMD shall be capable of recovering a conformant PMD signal from the medium, as described in related subclauses, with a frame error ratio (FER) \(\leq 3\%\) for PSDUs of 400 octets generated with pseudorandom data, for receiver input signal levels in the range from –20 dBm to the receiver sensitivity (as specified in 14.7.15.5), across the frequency band of operation.

**14.7.15.3 Receive center frequency acceptance range**

An IEEE 802.11 FHSS-compliant PMD shall meet all specifications with an input signal having a center frequency range of ±60 kHz from nominal.

**14.7.15.4 CCA power threshold**

In the presence of any IEEE 802.11-compliant 1 Mb/s FH PMD signal above –85 dBm that starts synchronously with respect to slot times as specified in 14.4.4.3.2, the PHY shall signal busy, with a 90% probability of detection, during the preamble within the CCA window. In the presence of any IEEE 802.11-compliant 1 Mb/s FH PMD signal above –85 dBm that starts asynchronously with respect to slot times as specified in 14.4.4.3.2, the PHY shall signal busy, with a 70% probability of detection, during the preamble within the CCA window. In the presence of any IEEE 802.11-compliant 1 Mb/s FH PMD signal above –65 dBm, the PHY shall signal busy,
with a 70% probability of detection, during random data within the CCA window. This specification applies to a PMD operating with a nominal EIRP of < 100 mW. A compliant PMD operating at a nominal output power greater than 100 mW shall use the following equation to define the CCA threshold, where \( P_t \) represents transmit power.

\[
\text{CCA threshold (preamble)} = -85 \text{ dBm} - \left[ 5 \times \log_{10} \left( \frac{P_t}{100 \text{ mW}} \right) \right] \text{ dBm}
\]

\[
\text{CCA threshold (random data)} = \text{CCA threshold (preamble)} + 20 \text{ dB}
\]

14.7.15.5 Receiver sensitivity

The sensitivity is defined as the minimum signal level required for an FER of 3% for PSDUs of 400 octets generated with pseudorandom data. The sensitivity shall be less than or equal to –80 dBm. The reference sensitivity is defined as –80 dBm for the 1 Mb/s FH PHY specifications.

14.7.15.6 Intermodulation

Intermodulation protection (IMp) is defined as the ratio of the minimum amplitude of one of two equal interfering signals to the desired signal amplitude, where the interfering signals are spaced 4 MHz and 8 MHz removed from the center frequency of the desired signal, both on the same side of center frequency. The IMp ratio is established at the interfering signal level that causes the FER of the receiver to be increased to 3% for PSDUs of 400 octets generated with pseudorandom data, when the desired signal is –77 dBm. Each interfering signal is modulated with the FH PMD modulation uncorrelated in time to each other or the desired signal. The PMD shall have the IMp for the interfering signal at 4 MHz and 8 MHz be ≥ 30 dB.

14.7.15.7 Desensitization (Dp)

Desensitization (Dp) is defined as the ratio to measured sensitivity of the minimum amplitude of an interfering signal that causes the FER at the output of the receiver to be increased to 3% for PSDUs of 400 octets generated with pseudorandom data, when the desired signal is –77 dBm. The interfering signal shall be modulated with the FHSS PMD modulation uncorrelated in time to the desired signal. The minimum Dp shall be as given in Table 14-19. The spectral purity of the interferer shall be sufficient to ensure that the measurement is limited by the receiver performance.

<table>
<thead>
<tr>

</tr>
<tr>
<td>( M = N \pm 3 ) or more</td>
<td>40 dB</td>
</tr>
</tbody>
</table>

\(^a\)Where \( M \) is the interferer frequency and \( N \) is the desired channel frequency.

14.7.15.8 Receiver radiation

The signal leakage when receiving shall not exceed –50 dBm EIRP in the operating frequency range. The FHSS PHY shall conform with out-of-band spurious emissions by regulatory bodies.
14.8 FHSS PMD sublayer, 2.0 Mb/s

14.8.1 Overview

Subclause 14.8 details the RF specification differences of the optional 2 Mb/s operation from the baseline 1 Mb/s PMD as contained in 14.7. Unless otherwise specified in 14.8, the compliant PMD shall also meet all requirements of 14.7 when transmitting at 2 Mb/s. When implementing the 2 Mb/s option, the preamble and PHY header shall be transmitted at 1 Mb/s. STAs implementing the 2 Mb/s option shall also be capable of transmitting and receiving PPDUs at 1 Mb/s.

14.8.2 4GFSK modulation

For an FHSS 2 Mb/s PMD, the modulation scheme shall be 4GFSK, with a nominal symbol-period bandwidth product (BT) of 0.5. The four-level deviation factor, defined as the frequency separation of adjacent symbols divided by symbol rate, h4, shall be related to the deviation factor of the 2GFSK modulation, h2, by the following equation:

\[
h_4 / h_2 = 20055 \pm 0.01
\]

An incoming bit stream at 2 Mb/s shall be converted to 2-bit words or symbols, with a rate of Fclk = 1 Msymbol/s. The first received bit shall be encoded as the LMB of the symbol in Table 14-20. The bits shall be encoded into symbols as shown in Table 14-20.

<table>
<thead>
<tr>

</tr>
<tr>
<td>10</td>
</tr>
<tr>
<td>11</td>
</tr>
<tr>
<td>01</td>
</tr>
<tr>
<td>00</td>
</tr>
</tbody>
</table>

NOTE—These deviation values are measured using the center symbol of 7 consecutive symbols of the same value. The instantaneous deviation will vary due to Gaussian pulse shaping.

The deviation factor h2 for 2GFSK (measured as the difference between frequencies measured in the middle of 0000 and 1111 patterns encountered in the SFD, divided by 1 MHz) is nominally 0.32. The deviation factor h2 shall be no less than 0.30 (with maximum dictated by regulatory bandwidth requirement). Accordingly, h4 (measured as a difference between the outermost frequencies, divided by 3, divided by 1 MHz) is nominally 0.45 \times 0.32 = 0.144, and shall be no less than 0.45 \times 0.3 = 0.135.
The modulation error shall be less than ±15 kHz at the midsymbol time for 4GFSK, from the frequency deviations specified above, for a symbol surrounded by identical symbols, and less than ±25 kHz for any symbol. The deviation is relative to the actual center frequency of the RF carrier. For definition purposes, the actual center frequency is the midfrequency between symbols 11 and 01. The actual center frequency shall be within ±60 kHz of the nominal channel center frequency defined in 14.7.5 and shall not vary by more than ±10 kHz/ms, from the start to end of the PPDU. The peak-to-peak variation of the actual center frequency over the PPDU shall not exceed 15 kHz. Symbols and terms used within this subclause are illustrated in Figure 14-17.

Figure 14-17—4GFSK transmit modulation

14.8.3 Frame structure for HS FHSS PHY

The high rate FHSS PPDU consists of PLCP preamble, PLCP header, and whitened PSDU. The PLCP preamble and PLCP header format are identical to the 1 Mb/s PHY, as described in 14.4.3. The whitened PSDU is transmitted in 2GFSK, 4GFSK, or potentially a higher-rate format, according to the rate chosen. The rate is indicated in a 3-bit field in a PLCP header, having a value of 1 or 2 bits per symbol (or Mb/s).

The PPDU is transmitted as four-level symbols, with the amount determined by number_of_symbols = (number_of_PSDU_octets × 8)/rate.

The input bits are scrambled according to the method in 14.4.3.4.

The scrambled bit stream is divided into groups of rate (1 or 2) consecutive bits. The bits are mapped into symbols according to Table 14-20.

A bias suppression algorithm is applied to the resulting symbol stream. The bias suppression algorithm is defined in 14.4.3.4, Figure 14-4, and Figure 14-7. A polarity control symbol is inserted prior to each block of 32 symbols (or less for the last block). The polarity control signals are 4GFSK symbols 10 or 00. The algorithm is equivalent to the case of 2GFSK, with the polarity symbol 2GFSK “1” replaced with 4GFSK symbol “10,” and the 2GFSK polarity symbol “0” replaced with a 4GFSK symbol “00.”

14.8.4 Channel data rate

The data rate for the whitened PSDU at the optional rate shall be 2.0 Mb/s ±50 ppm.
14.8.5 Input dynamic range

The PMD shall be capable of recovering a conformant PMD signal from the medium, as described in related subclauses, with an FER ≤ 3% for PSDUs of 400 octets generated with pseudorandom data, for receiver input signal levels in the range from –20 dBm to the receiver sensitivity (as specified in 14.8.6), across the frequency band of operation.

14.8.6 Receiver sensitivity

The sensitivity is defined as the minimum signal level required for an FER of 3% for PSDUs of 400 octets generated with pseudorandom data. The sensitivity shall be less than or equal to –75 dBm. The reference sensitivity is defined as –75 dBm for the 2 Mb/s FH PHY specifications.

14.8.7 IMp

IMp is defined as the ratio to –77 dBm of the minimum amplitude of one of the two equal-level interfering signals at 4 MHz and 8 MHz removed from center frequency, both on the same side of center frequency, that cause the FER of the receiver to be increased to 3% for PSDUs of 400 octets generated with pseudorandom data, when the desired signal is –72 dBm (3 dB above the specified sensitivity specified in 14.8.6). Each interfering signal is modulated with the FH 1 Mb/s PMD modulation uncorrelated in time to each other or the desired signal. The FHSS optional 2 Mb/s rate IMp shall be ≥ 25 dB.

14.8.8 Dp

Dp is defined as the ratio to measured sensitivity of the minimum amplitude of an interfering signal that causes the FER of the receiver to be increased to 3% for PSDUs of 400 octets generated with pseudorandom data, when the desired signal is –72 dB (3 dB above sensitivity specified in 14.8.6). The interfering signal shall be modulated with the FHSS PMD modulation uncorrelated in time to the desired signal. The minimum Dp shall be as given in Table 14-21.

14.9 FHSS PHY MIB

14.9.1 FH PHY attributes

Subclause 14.9 defines the attributes for the FHSS MIB. Table 14-22 lists these attributes and the default values. A description of each attribute is given in 14.9.2.

14.9.2 FH PHY attribute definitions

14.9.2.1 dot11PHYType

The dot11PHYType is FHSS. The LME uses this attribute to determine what PLCP and PMD are providing services to the MAC. It also is used by the MAC to determine what MAC sublayer management state machines need to be invoked to support the PHY. The value of this attribute is defined as the integer 01 to indicate the FHSS PHY.

14.9.2.2 dot11RegDomainsImplementedValue

Operational requirements for FHSS PHY are defined by agencies representing certain geographical regulatory domains. These regulatory agencies may define limits on various parameters that differ from region to region. This parameters may include dot11TxPowerLevels, and dot11MaxDwellTime, as well as the total number of frequencies in the hopping pattern. The values shown in Table 14-23 indicate regulatory agencies supported by this document.

</tbody>
</table>

NOTE—The column titled “Operational semantics” contains two types: static and dynamic. Static MIB attributes are fixed and cannot be modified for a given PHY implementation. MIB attributes defined as dynamic can be modified by some management entity. When an attribute is defined as dynamic, the column also shows which entity has control over the attribute. LME refers to the MLME, while PHY refers to the PLME.
Because a PLCP and PMD might be designed to support operation in more than one regulatory domain, this attribute can actually represent a list of agencies. This list may be one or more of the above agencies and shall be terminated using the null terminator. Upon activation of the PLCP and PMD, the information in this list shall be used to set the value of the dot11CurrentRegDomain attribute.

14.9.2.3 dot11CurrentRegDomain

The dot11CurrentRegDomain attribute for the FHSS PHY is defined as the regulatory domain under which the PMD is currently operating. This value shall be one of the values listed in the dot11RegDomainsImplementedValue list. This MIB attribute is managed by the LME.

14.9.2.4 dot11CurrentPowerState

The dot11CurrentPowerState attribute for the FHSS PHY allows the MLME to control the power state of the PHY. This attribute can be updated using the PLMESET.request primitive. The permissible values are ON and OFF.

14.9.2.5 dot11SupportedDataRatesTX

The dot11SupportedDataRatesTX attribute for the FHSS PHY is defined as a null terminated list of supported data rates in the transmit mode for this implementation. Table 14-24 shows the possible values appearing in the list.

<table>
<thead>
<tr>
<th>Code point</th>
<th>Data rate</th>
</tr>
</thead>

<tr>
<td>X'00'</td>
<td>Null terminator</td>
</tr>
</tbody>
</table>

14.9.2.7 aMPDUMaxLength

The aMPDUMaximumLength attribute for the FHSS PHY is defined as the maximum PSDU, in octets, that the PHY shall ever be capable of accepting. This value for the FHSS PHY is set at 4095 octets. The
recommended value for maximum PSDU length in an FHSS PHY system is 400 octets at 1 Mb/s and 800 octets at 2 Mb/s, which corresponds to a frame duration less than 3.5 ms. These values are optimized to achieve high performance in a variety of RF channel conditions, particularly with respect to indoor multipath, channel stability for moving STAs, and interference in the 2.4 GHz band.

14.9.2.8 dot11TxAntennaImplemented

The dot11TxAntennaImplemented attribute for the FHSS PHY is defined as a null terminated list of antennas that this implementation can use to transmit data. Table 14-26 shows the possible values appearing in the list, where $N \leq 255$.

Table 14-26—Number of transmit antennas

14.9.2.9 dot11CurrentTxAntenna

The dot11CurrentTxAntenna attribute for the FHSS PHY is used to describe the current antenna the implementation is using for transmission. This value should represent one of the antennas appearing in the dot11TxAntennaImplemented list.

14.9.2.10 dot11RxAntennaImplemented

The dot11RxAntennaImplemented attribute for the FHSS PHY is defined as a null terminated list of antennas that this implementation can use to receive data. In the FHSS PHY primitives, one of these values is passed as part of the PHY-RXSTART.indication primitive to the MAC sublayer for every received packet. Table 14-27 shows the possible values appearing in the list, where $N \leq 255$.

Table 14-27—Number of receive antennas

<td>Diversity available</td>
</tr>
<tr>
<td>X'02'</td>
<td>No diversity</td>
</tr>
<tr>
<td>X'03'</td>
<td>Control available</td>
</tr>
</tbody>
</table>

The value X'01' indicates that this implementation uses two or more antennas for diversity. The value X'02' indicates that the implementation has no diversity support. The value X'03' indicates that the choice of antennas used during diversity is programmable. (See 14.9.2.12.)

14.9.2.12 dot11DiversitySelectionRxImplemented

The dot11DiversitySelectionRxImplemented attribute for the FHSS PHY is a null terminated list describing the receive antenna or antennas currently in use during diversity and packet reception. Table 14-29 shows the possible values appearing in the list, where \( N \leq 255 \).

<table>
<thead>
<tr>
<th>Code point</th>
<th>Antenna number</th>

<tr>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>N</td>
<td>Rx Antenna ( N )</td>
</tr>
<tr>
<td>X'00'</td>
<td>Null terminator</td>
</tr>
</tbody>
</table>

The null terminated list enumerates one or more of the receive antennas listed in the dot11RxAntennaImplemented attribute. This attribute can be changed dynamically by the LME.

14.9.2.13 dot11NumberSupportedPowerLevelsImplemented

The dot11NumberSupportedPowerLevelsImplemented attribute for the FHSS PHY describes the number of power levels this implementation supports. This attribute is an integer of value 1 to 8, inclusive.

14.9.2.14 dot11TxPowerLevel1-8

Some implementations may provide up to eight different transmit power levels. The dot11TxPowerLevels attribute for the FHSS PHY is a list of up to eight power levels supported. Table 14-30 describes the list.
The dot11CurrentTxPowerLevel attribute for the FHSS PHY is defined as the current transmit output power level. This level shall be one of the levels implemented in the list of attributes called dot11TxPowerLevelN (where \(N\) is 1–8). This MIB attribute is also used to define the sensitivity of the CCA mechanism when the output power exceeds 100 mW. This MIB attribute is managed by the LME.

14.9.2.16 dot11HopTime

The dot11HopTime attribute for the FHSS PHY describes the time allocated for the PHY to change to a new frequency. For the FHSS PHY, this time period is 224 μs.

14.9.2.17 dot11CurrentChannelNumber

The dot11CurrentChannelNumber attribute for the FHSS PHY is defined as the current operating channel number of the PMD. The values of this attribute correspond to the values shown in Table 14-11. This MIB attribute is managed by the PLME and is updated as the result of a PLMESET.request primitive to dot11CurrentSet, dot11CurrentPattern, or dot11CurrentIndex.

14.9.2.18 dot11MaxDwellTime

The dot11MaxDwellTime attribute for the FHSS PHY is defined as the maximum time the PMD can dwell on a channel and meet the requirements of the current regulatory domain. For the FCC regulatory domain, this number is 390 TU (FCC = 400 ms). The recommended dwell time for the FHSS PHY is 19 TU.

14.9.2.19 dot11CurrentSet

The FHSS PHY contains three sets of hopping patterns. The dot11CurrentSet attribute for the FHSS PHY defines what set the STA is using to determine the hopping pattern. Its value is 1, 2, or 3. This attribute is managed by the PLME. When dot11MultiDomainCapabilityImplemented is true, this value may also be 0. A value of 0 indicates that the hopping pattern is to be obtained from the Hopping Pattern Table element most recently received in a Beacon or Probe Response frame.

14.9.2.20 dot11CurrentPattern

There are up to 78 patterns in each hopping set used by the FHSS PHY. The dot11CurrentPattern attribute for the FHSS PHY defines the \(x\) value used in Equation (14-1) in 14.7.8 to calculate the current channel

number. Its value has various ranges, always within the overall range of 0 to 77, depending on the dot11CurrentRegDomain. This attribute is managed by the PLME.

### 14.9.2.21 dot11CurrentIndex

The FHSS PHY addresses each channel in the selected hopping pattern through an index. The dot11CurrentIndex attribute for the FHSS PHY defines the $i$ value used in the equation for $f_x(i)$ in 14.7.8 to calculate the current channel number. Its value has various ranges, always within the overall range of 1 to 79, depending on the dot11CurrentRegDomain. This attribute is managed by the PLME.

### 14.9.2.22 dot11CurrentPowerState

The parameter dot11CurrentPowerState defines the operational state of the FHSS PHY. When this attribute has a value of X'01', the PHY is “OFF.” When this attribute has a value of X'02', the PHY is “ON.” This attribute is managed by the PLME.

### 14.10 FH PHY characteristics

Table 14-31 gives the static FH PHY characteristics, provided through the PLME-CHARACTERISTICS service primitive. The definitions of these characteristics are in 6.5.4.

15. Infrared (IR) PHY specification

15.1 Status of the Infrared PHY

The mechanisms described in this clause are obsolete. Consequently, this clause may be removed in a later revision of the standard.

This clause is no longer maintained and may not be compatible with all features of this standard.

15.2 Overview

15.2.1 General

The PHY for the infrared (IR) system is specified in this clause. The IR PHY uses near-visible light in the 850 nm to 950 nm range for signaling. This is similar to the spectral usage of both common consumer devices such as IR remote controls, as well as other data communications equipment, such as IR data association (IrDA) devices.

Unlike many other IR devices, however, the IR PHY is not directed. That is, the receiver and transmitter do not have to be aimed at each other and do not need a clear line-of-sight. This permits the construction of a true LAN system, whereas with an aimed system, it would be difficult or impossible to install a LAN because of physical constraints.

A pair of conformant IR devices would be able to communicate in a typical environment at a range up to about 10 m. This standard allows conformant devices to have more sensitive receivers, and this may increase range up to about 20 m.

The IR PHY relies on both reflected IR energy as well as line-of-sight IR energy for communications. Most designs anticipate that all of the energy at the receiver is reflected energy. This reliance on reflected IR energy is called diffuse IR transmission.

This standard specifies the transmitter and receiver in such a way that a conformant design operates well in most environments where there is no line-of-sight path from the transmitter to the receiver. However, in an environment that has few or no reflecting surfaces, and where there is no line-of-sight, an IR PHY system may suffer reduced range.

The IR PHY operates only in indoor environments. IR radiation does not pass through walls, and is significantly attenuated passing through most exterior windows. This characteristic can be used to “contain” an IR PHY in a single physical room, like a classroom or conference room. Different LANs using the IR PHY can operate in adjacent rooms separated only by a wall without interference, and without the possibility of eavesdropping.

At the time of this standard’s preparation, the only known regulatory standards that apply to the use of IR radiation are safety regulations, such as IEC 60825-1:1993 [B18] and ANSI Z136.1-1993 [B5]. While a conformant IR PHY device can be designed to also comply with these safety standards, conformance with this standard does not ensure conformance with other standards.

Worldwide, no frequency allocation or bandwidth allocation regulatory restrictions currently exist on IR emissions.
Emitter (typically LED) and detector (typically PIN diode) devices for IR communications are relatively inexpensive at the IR wavelengths specified in the IR PHY, and at the electrical operating frequencies required by this PHY.

While many other devices in common use also use IR emissions in the same optical band, these devices usually transmit IR intermittently and do not interfere with the proper operation of a compliant IR PHY. If such a device does interfere, by transmitting continuously and with a very strong signal, it can be physically isolated (placing it in a different room) from the IEEE 802.11 LAN.

15.2.2 Scope

The PHY services provided to the IEEE 802.11 WLAN MAC by the IR system are described in this clause. The IR PHY consists of two protocol functions as follows:

a) A PHY convergence function, which adapts the capabilities of the PMD system to the PHY service. This function is supported by the PLCP, which defines a method of mapping the IEEE 802.11 MPDUs into a framing format suitable for sending and receiving user data and management information between two or more STAs using the associated PMD system.

b) A PMD system, whose function defines the characteristics of, and method of transmitting and receiving data through, the WM between two or more STAs.

15.2.3 IR PHY functions

15.2.3.1 General

The IR PHY contains three functional entities: the PMD function, the PHY convergence function, and the layer management function. Each of these functions is described in detail below.

The IR PHY service is provided to the MAC entity at the STA through a SAP as described in Clause 7. For a visual guide to the relationship of the IR PHY to the remainder of the system, refer to Figure 4-14 (in 4.9).

15.2.3.2 PLCP sublayer

To allow the IEEE 802.11 MAC to operate with minimum dependence on the PMD sublayer, a PLCP sublayer is defined. This function simplifies the PHY service interface to the IEEE 802.11 MAC services. The PHY-specific preamble is normally associated with this convergence layer.

15.2.3.3 PMD sublayer

The PMD sublayer provides a CCA mechanism, transmission mechanism, and reception mechanism that are used by the MAC via the PLCP to send or receive data between two or more STAs.

15.2.3.4 PLME

The PLME performs management of the local PHY functions in conjunction with the MLME. See 15.5 for the MIB variables that may be accessed by the PHY entities and intralayer of higher level LMEs. These variables are accessed via the PLME-GET, PLME-SET, and PLME-RESET primitives defined in Clause 6.

15.2.4 Service specification method and notation

The models represented by figures and state diagrams are intended as illustrations of functions provided. It is important to distinguish between a model and a real implementation. The models are optimized for simplicity and clarity of presentation; the actual method of implementation is left to the discretion of the
IEEE 802.11 IR-PHY-compliant developer. Conformance to this standard is not dependent on following the model, and an implementation that follows the model closely may not be conformant.

Abstract services are specified here by describing the service primitives and parameters that characterize each service. This definition is independent of any particular implementation. In particular, the PHY-SAP operations are defined and described as instantaneous; however, this may be difficult to achieve in an implementation.

15.3 IR PLCP sublayer

15.3.1 General

While the PLCP sublayer and the PMD sublayer are described separately, the separation and distinction between these sublayers is artificial, and is not meant to imply that the implementation separates these functions. This distinction is made primarily to provide a point of reference from which to describe certain functional components and aspects of the PMD. The functions of the PLCP can be subsumed by a PMD sublayer; in this case, the PMD incorporates the PHY-SAP as its interface, and does not offer a PMD_SAP.

15.3.2 Overview

A convergence procedure is provided by which MPDUs are converted to and from PPDUs. During transmission, the MPDU (PSDU) is prepended with a PLCP preamble and PLCP header to create the PPDU. At the receiver, the PLCP preamble is processed and the internal data fields are processed to aid in demodulation and delivery of the MPDU (PSDU).

15.3.3 PLCP frame format

Figure 15-1 shows the format for the PPDU including the PLCP preamble, the PLCP header, and the PSDU. The PLCP preamble contains the following fields: SYNC and SFD. The PLCP header contains the following fields: data rate (DR), dc level adjustment (DCLA), length (LENGTH), and CRC. Each of these fields is described in detail in 15.3.5.

![Figure 15-1—PPDU frame format](image)

15.3.4 PLCP modulation and rate change

The PLCP preamble shall be transmitted using the basic pulse defined in 15.4.4.3. The PSDU, LENGTH, and CRC fields shall be transmitted using pulse position modulation (PPM). PPM maps bits in the octet into symbols: 16-PPM maps four bits into a 16-position symbol, and 4-PPM maps two bits into a 4-position symbol. The basic L-PPM TU is the slot. A slot corresponds to one of the L positions of a symbol and has a 250 ns duration. The PSDU, LENGTH, and CRC fields are transmitted at one of two bit rates: 1 Mb/s or 2 Mb/s. The DR field indicates the data rate that is used to transmit the PSDU, LENGTH, and CRC fields. The 1 Mb/s data rate uses 16-PPM (basic access rate), and the 2 Mb/s data rate uses 4-PPM (enhanced access rate). The transmitter and receiver shall initiate the modulation or demodulation indicated by the DR field starting with the first 4 bits (in 16-PPM) or 2 bits (in 4-PPM) of the LENGTH field. The PSDU transmission
rate is set by the DATARATE parameter in the PHY-TXSTART.request primitive. Any conformant IR PHY shall be capable of receiving at 1 Mb/s and 2 Mb/s. Transmission at 2 Mb/s is optional.

A PHY-TXSTART.request primitive that specifies a data rate that is not supported by a PHY instance causes the PHY to indicate an error to its MAC instance. A PHY is not permitted under any circumstance to transmit at a different rate than the requested rate.

15.3.5 PLCP field definitions

15.3.5.1 PLCP SYNC field

The SYNC field consists of a sequence of alternated presence and absence of a pulse in consecutive slots. The SYNC field has a minimum length of 57 L-PPM slots and a maximum length of 73 L-PPM slots and shall terminate with the absence of a pulse in the last slot. This field is provided so that the receiver can perform clock recovery (slot synchronization), automatic gain control (optional), signal-to-noise ratio estimation (optional), and diversity selection (optional).

The SYNC field is not modulated using L-PPM, but instead consists of transitions in L-PPM slots that would otherwise constitute an illegal symbol. See 15.4.3.2 for legal symbols.

15.3.5.2 PLCP SFD field

The SFD field length is four L-PPM slots and consists of the binary sequence 1001, where 1 indicates a pulse in the L-PPM slot and 0 indicates no pulse in the L-PPM slot. The leftmost bit shall be transmitted first. The SFD field is provided to indicate the start of the PLCP preamble and to perform bit and symbol synchronization.

The SFD field is not modulated using L-PPM, but instead consists of transitions in L-PPM slots that would otherwise constitute an illegal symbol.

15.3.5.3 PLCP DR field

The DR field indicates to the PHY the data rate that shall be used for the transmission or reception of the PSDU, LENGTH, and CRC fields. The transmitted value shall be provided by the PHY-TXSTART.request primitive as described in Clause 7. The DR field has a length of three L-PPM slots. The leftmost bit, as shown below, shall be transmitted first. The IR PHY currently supports two data rates defined by the slot pattern shown for the three L-PPM slots following the SFD, where 1 indicates a pulse in the L-PPM slot and 0 indicates no pulse in the L-PPM slot:

- 1 Mb/s: 000
- 2 Mb/s: 001

The DR field is not modulated using L-PPM, but instead consists of transitions in L-PPM slots that would otherwise constitute an illegal symbol.

15.3.5.4 PLCP DCLA field

The DCLA field is required to allow the receiver to stabilize the dc level after the SYNC, SFD, and DR fields. The leftmost bit, as shown below, shall be transmitted first. The length of the DCLA field is 32 L-PPM slots and consists of the contents shown, where 1 indicates a pulse in the L-PPM slot and 0 indicates no pulse in the L-PPM slot:

- 1 Mb/s: 00000000100000000000000000000000
- 2 Mb/s: 00100010001000100010001000100010
The DCLA field is not modulated using L-PPM, but instead consists of transitions in L-PPM slots that would otherwise constitute an illegal symbol.

15.3.5.5 PLCP LENGTH field

The LENGTH field is an unsigned 16-bit integer that indicates the number of octets to be transmitted in the PSDU. The transmitted value shall be provided by the PHY-TXSTART.request primitive as described in Clause 7. The LSB shall be transmitted first. This field is modulated and sent in L-PPM format. This field is protected by the CRC described in 15.3.5.6.

15.3.5.6 PLCP CRC field

The LENGTH field shall be protected by a 16-bit CRC. The CRC is the ones complement of the remainder generated by the modulo 2 division of the LENGTH field by the polynomial:

\[ x^{16} + x^{12} + x^5 + 1 \]

The protected bits are processed in transmit order. The MSB of the 16-bit CRC shall be transmitted first. This field shall be modulated and sent in L-PPM format. All CRC calculations shall be made prior to L-PPM encoding on transmission and after L-PPM decoding on reception.

15.3.5.7 PSDU field

This field is composed of a variable number of octets. The minimum is 0 (zero) and the maximum is 2500. The LSB of each octet shall be transmitted first. All the octets of this field shall be modulated and sent in L-PPM format.

15.3.6 PLCPs

15.3.6.1 Transmit PLCP

All commands issued by the MAC require that a confirmation primitive be issued by the PHY. The confirmation primitives provide flow control between the MAC and the PHY.

The transmit PLCP is as follows:

a) Based on the status of CCA, the MAC shall determine whether the channel is clear.

b) If the channel is clear, transmission of the PSDU shall be initiated by a PHY-TXSTART.request primitive with parameters LENGTH and DATARATE.

c) The PHY entity shall immediately initiate transmission of the PLCP preamble and PLCP header based on the LENGTH and DATARATE parameters passed in the PHY-TXSTART.request primitive. Once the PLCP preamble and PLCP header transmission is completed, the PHY entity shall issue a PHY-TXSTART.confirm primitive.

d) Each octet of the PSDU is passed from the MAC to the PHY by a single PHY-DATA.request primitive. Each PHY-DATA.request primitive shall be confirmed by the PHY with a PHY-DATA.confirm primitive before the next request can be made.

e) At the PHY each PSDU octet shall be divided into symbols of 2 bits or 4 bits each. The symbols shall be modulated using L-PPM and transmitted into the medium.

f) Transmission is terminated by the MAC through the PHY-TXEND.request primitive. The PHY shall confirm the resulting end of transmission with a PHY-TXEND.confirm primitive.
15.3.6.2 Receive PLCP

The receive PLCP is as follows:

a) CCA is provided to the MAC via the PHY-CCA.indication primitive. When the PHY senses activity on the medium, it shall indicate that the medium is busy with a PHY-CCA.indication primitive with a value of BUSY. This normally occurs during the SYNC field of the PLCP preamble.

b) The PHY entity shall begin searching for the SFD field. Once the SFD field is detected, the PHY entity shall attempt to receive the PLCP header. After receiving the DR and DCLA fields, the PHY shall initiate processing of the received CRC and LENGTH fields. The data rate indicated in the DR field applies to all symbols in the latter part of the received PSDU, commencing with the first symbol of the LENGTH field. The CRC shall be checked for correctness immediately after its reception.

c) If the CRC check fails, or the value received in the DR field is not one supported by the PHY, then a PHY-RXSTART.indication primitive shall not be issued to the MAC. When the medium is again free, the PHY shall issue a PHY-CCA.indication primitive with a value of IDLE.

d) If the PLCP preamble and PLCP header reception is successful, the PHY shall send a PHY-RXSTART.indication primitive to the MAC; this includes the parameters DATARATE and LENGTH.

In the absence of errors, the receiving PHY shall report the same length to its local MAC, in the RXVECTOR parameter of the PHY-RXSTART.indication primitive, that the peer MAC presented to its local PHY entity in the TXVECTOR parameter of its respective PHY-TXSTART.request primitive.

e) The received PSDU L-PPM symbols shall be assembled into octets and presented to the MAC using a series of PHY-DATA.indication primitives, one per octet.

f) Reception shall be terminated after the reception of the final symbol of the last PSDU octet indicated by the PLCP header’s LENGTH field. After the PHY-DATA.indication primitive for that octet is issued, the PHY shall issue a PHY-RXEND.indication primitive to its MAC.

g) After issuing the PHY-RXEND.indication primitive, and when the medium is no longer busy, the PHY shall issue a PHY-CCA.indication primitive with a value of IDLE.

15.3.6.3 CCA procedure

CCA is provided to the MAC via the PHY-CCA.indication primitive.

The CCA procedure is as follows:

a) When the PHY senses activity on the medium, a PHY-CCA.indication primitive with a value of BUSY shall be issued. This normally occurs during reception of the SYNC field of the PLCP preamble.

b) When the PHY senses that the medium is free, a PHY-CCA.indication primitive with a value of IDLE shall be issued.

c) At any time, the MAC may issue a PHY-CCARESET.request primitive, which resets the PHY’s internal CCA detection mechanism to the medium not-busy (IDLE) state. This primitive is acknowledged with a PHY-CCARESET.confirm primitive.

15.3.6.4 PMD_SAP peer-to-peer service primitive parameters

Several service primitives include a parameter vector. This vector shall be a list of parameters that may vary depending on PHY type. Table 15-1 indicates the parameters required by the MAC or IR PHY in each of the parameter vectors used for peer-to-peer interactions.
15.4 IR PMD sublayer

15.4.1 General

The IR PMD sublayer does not define PMD SAPs. The mechanism for communications between the PLCP and PMD sublayers, as well as the distinction between these two sublayers, if any, is left to implementers. In particular, it is possible to design and implement, in a conformant way, a single sublayer that subsumes the functions of both the PLCP and PMD, presenting only the PHY-SAP.

15.4.2 Overview

The PMD functional, electrical, and optical characteristics required for interoperability of implementations conforming to this specification are described in 15.4. The relationship of this specification to the entire IR PHY is shown in Figure 4-14 (in 4.9).

15.4.3 PMD operating specifications, general

15.4.3.1 General

General specifications for the IR PMD sublayer are provided in 15.4.3. These specifications apply to both the receive and transmit functions and general operation of a compliant IR PHY.

15.4.3.2 Modulation and channel data rates

Two modulation formats and data rates are specified for the IR PHY: a basic access rate and an enhanced access rate. The basic access rate is based on 1 Mb/s 16-PPM modulation. The 16-PPM encoding is specified in Table 15-2. Each group of 4 data bits is mapped to one of the 16-PPM symbols. The enhanced access rate is based on 2 Mb/s 4-PPM. The 4-PPM encoding is specified in Table 15-3. Each group of 2 data bits is mapped to one of the 4-PPM symbols. Transmission order of the symbol slots is from left to right, as shown in the table, where a 1 indicates in-band energy in the slot, and a 0 indicates the absence of in-band energy in the slot.

The data in Table 15-2 and Table 15-3 have been arranged (Gray coded) so that a single out-of-position-by-one error in the medium, caused, for example, by intersymbol interference, results in only a single bit error in the received data, rather than in a multiple bit error.

15.4.3.3 Octet partition and PPM symbol generation procedure

Because PPM is a block modulation method, with the block size less than a full octet, octets have to be partitioned prior to modulation (mapping into PPM symbols).

Octet partition depends on the PPM order being used.

Assume an octet is formed by eight bits numbered 7 6 5 4 3 2 1 0, where bit 0 is the LSB. Partition the octet as follows:

For 16-PPM, create two PPM symbols:
— The symbol using bits 3 2 1 0 shall be transmitted onto the medium first.
— The symbol using bits 7 6 5 4 shall be transmitted onto the medium last.

For 4-PPM, create four PPM symbols:
— The symbol using bits 1 0 shall be transmitted onto the medium first.
— The symbol using bits 3 2 shall be transmitted onto the medium second.
— The symbol using bits 5 4 shall be transmitted onto the medium third.
— The symbol using bits 7 6 shall be transmitted onto the medium last.

15.4.3.4 Operating environment

The IR PHY operates only in indoor environments. IR PHY interfaces cannot be exposed to direct sunlight. The IR PHY relies on reflected IR energy and does not require a line-of-sight between emitter and receiver.
in order to work properly. The range and bit error rate of the system may vary with the geometry of the environment and with natural and artificial illumination conditions.

15.4.4 PMD transmit specifications

15.4.4.1 Introduction

Subclause 15.4.4 describes the transmit functions and parameters associated with the PMD sublayer.

15.4.4.2 Transmitted peak optical power

The peak optical power of an emitted pulse shall be as specified in Table 15-4.

15.4.4.3 Basic pulse shape and parameters

The basic pulse width, measured between the 50% amplitude points, shall be 250 ±10 ns. The pulse rise time, measured between the 10% and 90% amplitude points, shall be no more than 40 ns. The pulse fall time, measured between the 10% and 90% amplitude points, shall be no more than 40 ns. The edge jitter, defined as the absolute deviation of the edge from its correct position, shall be no more than 10 ns. The basic pulse shape is shown in Figure 15-2.

![Figure 15-2—Basic pulse shape](image-url)
15.4.4.4 Emitter radiation pattern mask

The standard contains two emitter radiation pattern masks. Mask 1 is defined in Table 15-5 and illustrated in Figure 15-3.

Following is a description of how to interpret the Mask 1 table and figure. Position the conformant Mask 1 device in its recommended attitude. Define the conformant Mask 1 device axis as the axis passing through the emitter center and having the direction perpendicular to the floor. The mask represents the irradiance normalized to the total peak emitted power, as a function of the angle between the conformant Mask 1 device axis and the axis from the emitter center to the test receiver center (declination angle). The distance between emitter and test receiver is 1 m. The test receiver normal is always aimed at the emitter center. The azimuth angle is a rotation angle on the conformant device axis.

A device is conformant if for any azimuth angle its radiation pattern as a function of declination angle falls within the pattern mask.

Figure 15-5 is a description of how to interpret the Mask 2 table with reference to Figure 15-4.

Position the conformant Mask 2 device in its recommended attitude. Define the conformant Mask 2 device axis as passing through the emitter center and having the direction relative to the device as defined by the manufacturer. The declination angle plane is as defined by the manufacturer. The mask represents the irradiance normalized to the peak emitted power on the conformant Mask 2 device axis, as a function of the
angle between the conformant device axis and the axis from the emitter center to the test receiver center (declination angle) in the declination plane. The distance between emitter and test receiver is 1 m. The test receiver normal is always aimed at the emitter center. The pitch angle is an angle relative to the conformant device axis which is perpendicular to the declination plane.

The device is conformant if, for a pitch angle of 0 degrees, at any declination angle from 0 to 100 degrees, and if, for any declination angle from 0 to 60 degrees, at any pitch angle from 0 to 20 degrees, its radiation pattern as a function of angle falls within the pattern mask.

Other radiation patterns are for future study.

15.4.4.5 Optical emitter peak wavelength

The optical emitter peak wavelength shall be between 850 nm and 950 nm.

15.4.4.6 Transmit spectrum mask

Define the transmit spectrum of a transmitter as the Fourier Transform, or equivalent, of a voltage (or current) signal whose amplitude, as a function of time, is proportional to the transmitted optical power.

The transmit spectrum of a conformant transmitter shall be 20 dB below its maximum for all frequencies above 15 MHz. The transmit spectrum mask is shown in Figure 15-6.

![Figure 15-6—Transmit spectrum mask](image)

15.4.5 PMD receiver specifications

15.4.5.1 Introduction

Subclause 15.4.5 describes the receive functions and parameters associated with the PMD sublayer.

15.4.5.2 Receiver sensitivity

The receiver sensitivity, defined as the minimum irradiance (in mW/cm²) at the photodetector plane required for a FER of $4 \times 10^{-5}$ with a PSDU of 512 octets and with an unmodulated background IR source between 800 nm and 1000 nm with a level of 0.1 mW/cm², shall be
1 Mb/s: $2 \times 10^{-5}$ mW/cm$^2$
2 Mb/s: $8 \times 10^{-5}$ mW/cm$^2$

15.4.5.3 Receiver dynamic range

The receiver dynamic range, defined as the ratio between the maximum and minimum irradiance at the plane normal to the receiver axis that assures an FER lower than or equal to $4 \times 10^{-5}$ with a PSDU of 512 octets and with an unmodulated background IR source between 800 nm and 1000 nm with a level of 0.1 mW/cm$^2$, shall be $\geq 30$ dB.

15.4.5.4 Receiver field of view (FOV)

The receiver axis is defined as the direction of incidence of the optical signal at which the received optical power is maximum.

The received optical power shall be greater than the values given in Table 15-7, at the angles indicated, where “angle of incidence” is the angle of the optical signal relative to the receiver axis, and “received power” is the received optical power as a percentage of that measured at the receiver axis.

<td>$\geq 10%$</td>
</tr>
</tbody>
</table>

15.4.6 ED, CS, and CCA definitions

15.4.6.1 ED signal

The ED signal shall be set true when IR energy variations in the band between 1 MHz and 10 MHz exceed 0.001 mW/cm$^2$.

The ED shall operate independently of the CS. The ED shall not be asserted at the minimum signal level specified in 15.4.5.2, which is below the level specified in 15.4.6.

This signal is not directly available to the MAC.

15.4.6.2 CS signal

The CS shall be asserted by the PHY when it detects and locks onto an incoming PLCP preamble signal. Conforming PHYs shall assert this condition within the first 12 µs of signal reception, at the minimum signal level equal to the receiver sensitivity specified in 15.4.5.2, with a background IR level as specified in 15.4.5.2.

The CS shall be deasserted by the PHY when the receiving conformant device loses carrier lock.

NOTE—The 12 µs specification is somewhat less than the minimum length of the PLCP SYNC interval, which is 14.25 µs.
The CS shall operate independently of the ED and shall not require a prior ED before the acquisition and assertion of CS. This permits reception of signals at the minimum signal level specified in 15.4.5.2, even though these signals fall below the ED level.

This signal is not directly available to the MAC.

15.4.6.3 CCA

CCA shall be asserted IDLE by the PHY when the CS and the ED are both false, or when ED has been continuously asserted for a period of time defined by the product of dot11CCAWatchdogTimerMax and dot11CCAWatchdogCountMax without CS becoming active. When either CS or ED go true, CCA is indicated as BUSY to the MAC via the primitive PHY-CCA.indication primitive. CS and ED behavior are defined in 15.4.6.2.

Normally, CCA is held BUSY throughout the period of the PLCP header. After receiving the last PLCP bit and the first data octet, the PHY shall signal PHY-RXSTART.indication primitive with the parameters LENGTH and RATE. CCA shall be held BUSY until the number of octets specified in the decoded PLCP header are received. At that time the PHY shall signal PHY-RXEND.indication primitive. The CCA may remain BUSY after the end of data if some form of energy is still being detected. The PHY signals PHY-CCA.indication primitive with a value of IDLE only when the CCA goes CLEAR.

The transition of CCA from BUSY to IDLE is indicated to the MAC via the primitive PHY-CCA.indication primitive.

If CS and ED go false before the PHY generates a PHY-RXSTART.indication primitive, CCA is set to IDLE and immediately signaled to the MAC via a PHY-CCA.indication primitive with a value of IDLE. If CS and ED go false after the PHY has signaled PHY-RXSTART.indication, implying that the PLCP header has been properly decoded, then the PHY shall not signal a change in state of CCA until the proper interval has passed for the number of octets indicated by the received PLCP LENGTH field. At that time, the PHY shall generate a PHY-RXEND.indication primitive with an RXERROR parameter of CarrierLost followed by a PHY-CCA.indication primitive with a value of IDLE.

The transition of CCA from CLEAR to BUSY resets the CCA watchdog timer and CCA watchdog counter. dot11CCAWatchdogTimerMax and dot11CCAWatchdogCountMax are parameters available via MIB entries and can be read and set via the LME.

Rise and fall times of CCA relative to the OR’ing of the CS and ED signals shall be less than 30 ns. CS and ED are both internal signals to the PHY and are not available directly to the MAC, nor are they defined at any exposed interface.

15.4.6.4 CHNL_ID

For the IR PHY, CHNL_ID = X’01’ is defined as the baseband modulation method. All other values are not defined.

15.5 PHY attributes

PHY attributes have allowed values and default values that are PHY dependent. Table 15-8 and Table 15-9 describe those values, and further specify whether they are permitted to vary from implementation to implementation.

Table 15-8 does not provide the definition of the attributes, but only provides the IR PHY-specific values for the attributes whose definitions are in C.
The static IR PHY characteristics, provided through the PLME-CHARACTERISTICS service primitive, are shown in Table 15-9. The definitions of these characteristics are in 6.5.4.

16. DSSS PHY specification for the 2.4 GHz band designated for ISM applications

16.1 Overview

16.1.1 General

The PHY for the DSSS system is described in this clause. The RF LAN system is aimed for the 2.4 GHz band designated for ISM applications.

The DSSS system provides a WLAN with both a 1 Mb/s and a 2 Mb/s data payload communication capability. The DSSS system uses baseband modulations of differential binary phase shift keying (DBPSK) and differential quadrature phase shift keying (DQPSK) to provide the 1 Mb/s and 2 Mb/s data rates, respectively.

16.1.2 Scope

The PHY services provided to the IEEE 802.11 WLAN MAC by the 2.4 GHz DSSS system are described in this clause. The DSSS PHY consists of two protocol functions:

a) A PHY convergence function, which adapts the capabilities of the PMD system to the PHY service. This function shall be supported by the PLCP, which defines a method of mapping the IEEE 802.11 MPDUs into a framing format suitable for sending and receiving user data and management information between two or more STAs using the associated PMD system.

b) A PMD system, whose function defines the characteristics of, and method of transmitting and receiving data through, a WM between two or more STAs each using the DSSS system.

16.1.3 DSSS PHY functions

16.1.3.1 General

The 2.4 GHz DSSS PHY architecture is depicted in the reference model shown in Figure 4-14 (in 4.9). The DSSS PHY contains three functional entities: the PMD function, the PHY convergence function, and the layer management function. Each of these functions is described in detail in the following subclauses.

The DSSS PHY service shall be provided to the MAC through the PHY service primitives described in Clause 7.

16.1.3.2 PLCP sublayer

To allow the IEEE 802.11 MAC to operate with minimum dependence on the PMD sublayer, a PLCP sublayer is defined. This function simplifies the PHY service interface to the IEEE 802.11 MAC services.

16.1.3.3 PMD sublayer

The PMD sublayer provides a means to send and receive data between two or more STAs. This clause is concerned with the 2.4 GHz ISM bands using direct sequence modulation.

16.1.3.4 PLME

The PLME performs management of the local PHY functions in conjunction with the MLME.
16.1.4 Service specification method and notation

The models represented by figures and state diagrams are intended to be illustrations of functions provided. It is important to distinguish between a model and a real implementation. The models are optimized for simplicity and clarity of presentation; the actual method of implementation is left to the discretion of the IEEE 802.11 DSSS-PHY-compliant developer.

The service of a layer or sublayer is a set of capabilities that it offers to a user in the next-higher layer (or sublayer). Abstract services are specified here by describing the service primitives and parameters that characterize each service. This definition is independent of any particular implementation.

16.2 DSSS PLCP sublayer

16.2.1 Overview

Subclause 16.2 provides a convergence procedure in which MPDUs are converted to and from PPDUs. During transmission, the MPDU shall be prepended with a PLCP preamble and header to create the PPDU. At the receiver, the PLCP preamble and header are processed to aid in demodulation and delivery of the MPDU.

16.2.2 PLCP frame format

Figure 16-1 shows the format for the PPDU including the DSSS PLCP preamble, the DSSS PLCP header, and the MPDU. The PLCP preamble contains the following fields: SYNC and SFD. The PLCP header contains the following fields: IEEE 802.11 Signaling (SIGNAL), IEEE 802.11 Service (SERVICE), length (LENGTH), and CRC-16 (CRC). Each of these fields is described in detail in 16.2.3.

![PLCP frame format diagram](image)

**Figure 16-1—PLCP frame format**

16.2.3 PLCP field definitions

16.2.3.1 General

The entire PLCP preamble and header shall be transmitted using the 1 Mb/s DBPSK modulation described in 16.4.7. All transmitted bits shall be scrambled using the feedthrough scrambler described in 16.2.4.

16.2.3.2 PLCP SYNC field

The SYNC field shall consist of 128 bits of scrambled ones. This field shall be provided so that the receiver can perform the necessary operations for synchronization.
16.2.3.3 PLCP SFD

The SFD shall be provided to indicate the start of PHY-dependent parameters within the PLCP preamble. The SFD shall be a 16-bit field, X'F3A0' (MSB to LSB). The LSB shall be transmitted first in time.

16.2.3.4 PLCP IEEE 802.11 SIGNAL field

The 8-bit IEEE 802.11 SIGNAL field indicates to the PHY the modulation that shall be used for transmission (and reception) of the MPDU. The data rate shall be equal to the signal field value multiplied by 100 kbit/s. The DSSS PHY currently supports two mandatory modulation services given by the following 8-bit words, where the LSB shall be transmitted first in time:

a) X'0A' (MSB to LSB) for 1 Mb/s DBPSK
b) X'14' (MSB to LSB) for 2 Mb/s DQPSK

The DSSS PHY rate change capability is described in 16.2.5. This field shall be protected by the CRC-16 FCS described in 16.2.3.7.

16.2.3.5 PLCP IEEE 802.11 SERVICE field

The 8-bit IEEE 802.11 SERVICE field shall be reserved for future use. The LSB shall be transmitted first in time. This field shall be protected by the CRC-16 FCS described in 16.2.3.7.

16.2.3.6 PLCP LENGTH field

The PLCP LENGTH field shall be an unsigned 16-bit integer that indicates the number of microseconds (16 to $2^{16}-1$ as defined by aMPDUMaxLength) required to transmit the MPDU. The transmitted value shall be determined from the LENGTH parameter in the TXVECTOR issued with the PHY-TXSTART.request primitive described in 7.3.5.5. The LENGTH field provided in the TXVECTOR is in octets and is converted to microseconds for inclusion in the PLCP LENGTH field. The LSB shall be transmitted first in time. This field shall be protected by the CRC-16 FCS described in 16.2.3.7.

16.2.3.7 PLCP CRC field

The IEEE 802.11 SIGNAL, IEEE 802.11 SERVICE, and LENGTH fields shall be protected with a CRC-16 FCS. The CRC-16 FCS shall be the ones complement of the remainder generated by the modulo 2 division of the protected PLCP fields by the polynomial:

$$ x^{16} + x^{12} + x^5 + 1 $$

The protected bits shall be processed in transmit order. All FCS calculations shall be made prior to data scrambling.

As an example, the SIGNAL, SERVICE, and LENGTH fields for a DBPSK signal with a packet length of 192 µs (24 octets) would be given by the following:

0101 0000 0000 0000 0000 0011 0000 0000 (leftmost bit transmitted first in time)

The ones complement FCS for these protected PLCP preamble bits would be the following:

0101 1011 0101 0111 (leftmost bit transmitted first in time)

Figure 16-2 depicts this example.
An illustrative example of the CRC-16 FCS using the information from Figure 16-2 follows in Figure 16-3.

Figure 16-2—CRC-16 implementation

Figure 16-3—Example CRC calculation
16.2.4 PLCP/DSSS PHY data scrambler and descrambler

The polynomial \( G(z) = z^{-7} + z^{-4} + 1 \) shall be used to scramble all bits transmitted by the DSSS PHY. The feedthrough configuration of the scrambler and descrambler is self-synchronizing, which requires no prior knowledge of the transmitter initialization of the scrambler for receive processing. Figure 16-4 and Figure 16-5 show typical implementations of the data scrambler and descrambler, but other implementations are possible.

The scrambler should be initialized to any state except all ones when transmitting.

![Data scrambler diagram](image)

Scrambler Polynomial: \( G(z) = z^{-7} + z^{-4} + 1 \)

![Data descrambler diagram](image)

Descrambler Polynomial: \( G(z) = z^{-7} + z^{-4} + 1 \)

16.2.5 PLCP data modulation and modulation rate change

The PLCP preamble shall be transmitted using the 1 Mb/s DBPSK modulation. The IEEE 802.11 SIGNAL field shall indicate the modulation that shall be used to transmit the MPDU. The transmitter and receiver shall initiate the modulation indicated by the IEEE 802.11 SIGNAL field starting with the first symbol (1 bit for DBPSK or 2 bits for DQPSK) of the MPDU. The MPDU transmission rate shall be set by the DATARATE parameter in the TXVECTOR issued with the PHY-TXSTART.request primitive described in 16.4.4.2.

16.2.6 Transmit PLCP

The transmit PLCP is shown in Figure 16-6.

In order to transmit data, PHY-TXSTART.request primitive shall be enabled so that the PHY entity shall be in the transmit state. Further, the PHY shall be set to operate at the appropriate channel through STA management via the PLME. Other transmit parameters such as DATARATE, TX antenna, and TX power are set via the PHY-SAP with the PHY-TXSTART.request(TXVECTOR) primitive as described in 16.4.4.3.
Based on the status of CCA indicated by PHY-CCA.indication primitive, the MAC assesses that the channel is clear. A clear channel shall be indicated by PHY-CCA.indication(IDLE) primitive. If the channel is clear, transmission of the PPDU shall be initiated by issuing the PHY-TXSTART.request(TXVECTOR) primitive. The TXVECTOR elements for the PHY-TXSTART.request primitive are the PLCP header parameters SIGNAL (DATARATE), SERVICE, and LENGTH, and the PMD parameters of TX_ANTENNA, TXPWR_LEVEL, and TIME_OF_DEPARTURE_REQUESTED. The PLCP header parameter LENGTH is calculated from the TXVECTOR element by multiplying by 8 for 1 Mb/s and by 4 for 2 Mb/s.

The PLCP shall issue PMD_ANTSEL, PMD_RATE, and PMD_TXPWR_LVL primitives to configure the PHY. The PLCP shall then issue a PMD_TXSTART.request primitive and the PHY entity shall immediately initiate data scrambling and transmission of the PLCP preamble based on the parameters passed in the PHY-TXSTART.request primitive. The time required for transmit power-on ramp described in 16.4.7.8 shall be included in the PLCP SYNC field. If dot11MgmtOptionTODImplemented and dot11MgmtOptionTODActivated are set to true and the TXVECTOR parameter TIME_OF_DEPARTURE_REQUESTED is true, then the PLCP shall issue a PHY_TXSTART.confirm(TXSTATUS) primitive to the MAC, forwarding the TIME_OF_DEPARTURE corresponding to the time when the first frame energy is sent by the transmitting port, and the TIME_OF_DEPARTURE_ClockRate parameters within the TXSTATUS vector. If dot11MgmtOptionTimingMsmtActivated is true, then the PLCP shall forward the value of TX_START_OF_FRAME_OFFSET in TXSTATUS vector. Once the PLCP preamble transmission is complete, data shall be exchanged between the MAC and the PHY by a series of PHY-DATA.request(DATA) primitives issued by the MAC and PHY-DATA.confirm primitives issued by the PHY. The modulation rate change, if any, shall be initiated with the first data symbol of the MPDU as described in 16.2.5. The PHY proceeds with MPDU transmission through a series of data octet transfers from the MAC. At the PMD layer, the data octets are sent in LSB-to-MSB order and presented to the PHY through PMD_DATA.request primitives. Transmission can be prematurely terminated by the MAC through the PHY-TXEND.request primitive. PHY-TXSTART shall be disabled by the issuance of the PHY-TXEND.request primitive. Normal termination occurs after the transmission of the final bit of the last MPDU octet according to the number supplied in the TXVECTOR LENGTH field. The packet transmission shall be completed and the PHY entity shall enter the receive state (i.e., PHY-TXSTART shall be disabled). It is recommended that chipping continue during power-down. Each PHY-TXEND.request primitive is acknowledged with a PHY-TXEND.confirm primitive from the PHY.
A typical state machine implementation of the transmit PLCP is provided in Figure 16-7.

**Figure 16-7—PLCP transmit state machine**

16.2.7 Receive PLCP

The receive PLCP is shown in Figure 16-8.

**Figure 16-8—Receive PLCP**
In order to receive data, PHY-TXSTART.request primitive shall be disabled so that the PHY entity is in the receive state. Further, through STA management via the PLME, the PHY is set to the appropriate channel and the CCA method is chosen. Other receive parameters such as RSSI, RCPI, signal quality (SQ), and indicated Datarate may be accessed via the PHY-SAP.

Upon receiving the transmitted energy, according to the selected CCA mode, the PMD_ED shall be enabled (according to 16.4.8.5) as the RSSI reaches the ED_THRESHOLD and/or PMD_CS shall be enabled after code lock is established. These conditions are used to indicate activity to the MAC via PHY-CCA.indication primitive according to 16.4.8.5. A PHY-CCA.indication(BUSY) primitive shall be issued for energy detection (ED) and/or code lock prior to correct reception of the PLCP frame. The PMD primitives PMD_SQ and PMD_RSSI are issued to update the RSSI and SQ parameters reported to the MAC.

After a PHY-CCA.indication primitive is issued, the PHY entity shall begin searching for the SFD field. Once the SFD field is detected, CRC-16 processing shall be initiated and the PLCP IEEE 802.11 SIGNAL, IEEE 802.11 SERVICE and LENGTH fields are received. The CRC-16 FCS shall be processed. If the CRC-16 FCS check fails, the PHY receiver shall return to the RX IDLE state as depicted in Figure 16-9. Should the status of CCA return to the IDLE state during reception prior to completion of the full PLCP processing, the PHY receiver shall return to the RX IDLE state.

If the PLCP header reception is successful (and the SIGNAL field is completely recognizable and supported), a PHY-RXSTART.indication(RXVECTOR) primitive shall be issued. If dot11MgmtOptionTimingMsmtActivated is true, the PLCP shall do the following:

- Complete receiving the PLCP header and verify the validity of the PLCP Header.
- If the PLCP header reception is successful (and the SIGNAL field is completely recognizable and supported), a PHY-RXSTART.indication(RXVECTOR) shall be issued and RX_START_OF_FRAME_OFFSET parameter within the RXVECTOR shall be forwarded (see 16.4.4.3).

NOTE—The RX_START_OF_FRAME_OFFSET value is used as described in 6.3.57 in order to estimate when the start of the preamble for the incoming frame was detected on the medium at the receive antenna port.

The RXVECTOR associated with this primitive includes the SIGNAL field, the SERVICE field, the MPDU length in octets (calculated from the LENGTH field in microseconds), the antenna used for receive (RX_ANTENNA), RSSI, RCPI, and SQ.

The received MPDU bits are assembled into octets and presented to the MAC using a series of PHY-DATA.indication(DATA) primitive exchanges. The rate change indicated in the IEEE 802.11 SIGNAL field shall be initiated with the first symbol of the MPDU as described in 16.2.5. The PHY proceeds with MPDU reception. After the reception of the final bit of the last MPDU octet indicated by the PLCP preamble LENGTH field, the receiver shall be returned to the RX IDLE state as shown in Figure 16-9. A PHY-RXEND.indication(NoError) primitive shall be issued. A PHY-CCA.indication(IDLE) primitive shall be issued following a change in PHY carrier sense (PHYCS) and/or PHY energy detection (PHYED) according to the selected CCA method.

In the event that a change in PHYCS or PHYED would cause the status of CCA to return to the IDLE state before the complete reception of the MPDU as indicated by the PLCP LENGTH field, the error condition shall be reported to the MAC using a PHY-RXEND.indication(CarrierLost) primitive. The DSSS PHY shall ensure that the CCA indicates a busy medium for the intended duration of the transmitted packet.

If the PLCP header is successful, but the indicated rate in the SIGNAL field is not receivable, a PHY-RXSTART.indication primitive shall not be issued. The PHY shall indicate the error condition by issuing a PHY-RXEND.indication(UnsupportedRate) primitive. If the PLCP header is successful, but the SERVICE field is out of IEEE 802.11 DSSS specification, a PHY-RXSTART.indication primitive shall not be issued. The PHY shall indicate the error condition using a PHY-RXEND.indication(FormatViolation) primitive.
Also, in both cases, the DSSS PHY shall ensure that the CCA indicates a busy medium for the intended duration of the transmitted frame as indicated by the LENGTH field. The intended duration is indicated by the LENGTH field (length × 1 µs).

A typical state machine implementation of the receive PLCP is provided in Figure 16-9.

Figure 16-9—PLCP receive state machine
16.3 DSSS PLME

16.3.1 PLME_SAP sublayer management primitives

Table 16-1 lists the MIB attributes that may be accessed by the PHY entities and intralayer of higher level LMEs. These attributes are accessed via the PLME-GET, PLME-SET, and PLME-RESET primitives defined in Clause 6.

16.3.2 DSSS PHY MIB

All DSSS PHY MIB attributes are defined in Clause 7, with specific values defined in Table 16-1.

16.4 DSSS PMD sublayer

16.4.1 Scope and field of application

Subclause 16.4 describes the PMD services provided to the PLCP for the DSSS PHY. Also defined in 16.4 are the functional, electrical, and RF characteristics required for interoperability of implementations conforming to this standard. The relationship of this standard to the entire DSSS PHY is shown in Figure 16-10.

Table 16-2—DS PHY characteristics (continued)

16.4.2 Overview of service

The DSSS PMD sublayer accepts PLCP sublayer service primitives and provides the actual means by which data shall be transmitted or received from the medium. The combined function of DSSS PMD sublayer primitives and parameters for the receive function results in a data stream, timing information, and associated receive signal parameters being delivered to the PLCP sublayer. A similar functionality shall be provided for data transmission.
16.4.3 Overview of interactions

The primitives associated with the IEEE 802.11 PLCP sublayer to the DSSS PMD fall into two basic categories:

a) Service primitives that support PLCP peer-to-peer interactions, and
b) Service primitives that have local significance and that support sublayer-to-sublayer interactions.

16.4.4 Basic service and options

16.4.4.1 General

All of the service primitives described in 16.4.4 are considered mandatory unless otherwise specified.

16.4.4.2 PMD_SAP peer-to-peer service primitives

Table 16-3 indicates the primitives for peer-to-peer interactions.

16.4.4.3 PMD_SAP peer-to-peer service primitive parameters

Several service primitives include a parameter vector. This vector shall be a list of parameters that may vary depending on PHY type. Table 16-4 indicates the parameters required by the MAC or DSSS PHY in each of the parameter vectors used for peer-to-peer interactions.

</table>
16.4.5 PMD_SAP detailed service specification

16.4.5.1 Introduction

The services provided by each PMD primitive are described in 16.4.5.2 to 16.4.5.16.

16.4.5.2 PMD_DATA.request

16.4.5.2.1 Function

This primitive defines the transfer of data from the PLCP sublayer to the PMD entity.

16.4.5.2.2 Semantics of the service primitive

The primitive shall provide the following parameter:

\[
\text{PMD\_DATA}\text{.request}(\text{TXD\_UNIT})
\]

The TXD_UNIT parameter takes on the value of either 1 or 0 for DBPSK modulation or the dibit combination 00, 01, 11, or 10 for DQPSK modulation. This parameter represents a single block of data, which, in turn, shall be used by the PHY to be differentially encoded into a DBPSK or DQPSK transmitted symbol. The symbol itself shall be spread by the PN code prior to transmission.

16.4.5.2.3 When generated

This primitive shall be generated by the PLCP sublayer to request transmission of a symbol. The data clock for this primitive shall be supplied by the PMD layer based on the PN code repetition.

16.4.5.2.4 Effect of receipt

The PMD performs the differential encoding, PN code modulation, and transmission of the data.

16.4.5.3 PMD_DATA.indication

16.4.5.3.1 Function

This primitive defines the transfer of data from the PMD entity to the PLCP sublayer.

16.4.5.3.2 Semantics of the service primitive

The primitive shall provide the following parameter:

\[
\text{PMD\_DATA}\text{.indication}(\text{RXD\_UNIT})
\]

The RXD_UNIT parameter takes on the value of 1 or 0 for DBPSK modulation or as the dibit 00, 01, 11, or 10 for DQPSK modulation. This parameter represents a single symbol that has been demodulated by the PMD entity.

16.4.5.3.3 When generated

This primitive, which is generated by the PMD entity, forwards received data to the PLCP sublayer. The data clock for this primitive shall be supplied by the PMD layer based on the PN code repetition.
16.4.5.3.4 Effect of receipt

The PLCP sublayer either interprets the bit or bits that are recovered as part of the PLCP or passes the data to the MAC sublayer as part of the MPDU.

16.4.5.4 PMD_TXSTART.request

16.4.5.4.1 Function

This primitive, which is generated by the PHY PLCP sublayer, initiates PPDU transmission by the PMD layer.

16.4.5.4.2 Semantics of the service primitive

The semantics of this primitive are as follows:

PMD_TXSTART.request

16.4.5.4.3 When generated

This primitive shall be generated by the PLCP sublayer to initiate the PMD layer transmission of the PPDU. The PHY-DATA.request primitive shall be provided to the PLCP sublayer prior to issuing the PMD_TXSTART command.

16.4.5.4.4 Effect of receipt

PMD_TXSTART initiates transmission of a PPDU by the PMD sublayer.

16.4.5.5 PMD_TXEND.request

16.4.5.5.1 Function

This primitive, which is generated by the PHY PLCP sublayer, ends PPDU transmission by the PMD layer.

16.4.5.5.2 Semantics of the service primitive

The semantics of the primitive are as follows:

PMD_TXEND.request

16.4.5.5.3 When generated

This primitive shall be generated by the PLCP sublayer to terminate the PMD layer transmission of the PPDU.

16.4.5.5.4 Effect of receipt

PMD_TXEND terminates transmission of a PPDU by the PMD sublayer.

16.4.5.6 PMD_ANTSEL.request

16.4.5.6.1 Function

This primitive, which is generated by the PHY PLCP sublayer, selects the antenna used by the PHY for transmission or reception (when diversity is disabled).
16.4.5.6.2 Semantics of the service primitive

The primitive shall provide the following parameter:

```c
PMD_ANTSEL.request(ANT_STATE)
```

ANT_STATE selects which of the available antennas should be used for transmit. The number of available antennas shall be determined from the MIB table parameters aSuprtRxAntennas and aSuprtTxAntennas.

16.4.5.6.3 When generated

This primitive shall be generated by the PLCP sublayer to select a specific antenna for transmission or reception (when diversity is disabled).

16.4.5.6.4 Effect of receipt

PMD_ANTSEL immediately selects the antenna specified by ANT_STATE.

16.4.5.7 PMD_ANTSEL.indication

16.4.5.7.1 Function

This primitive, which is generated by the PHY PLCP sublayer, reports the antenna used by the PHY for reception of the most recent packet.

16.4.5.7.2 Semantics of the service primitive

The primitive shall provide the following parameter:

```c
PMD_ANTSEL.indication(ANT_STATE)
```

ANT_STATE reports which of the available antennas was used for reception of the most recent packet.

16.4.5.7.3 When generated

This primitive shall be generated by the PLCP sublayer to report the antenna used for the most recent packet reception.

16.4.5.7.4 Effect of receipt

PMD_ANTSEL immediately reports the antenna specified by ANT_STATE.

16.4.5.8 PMD_TXPWRLVL.request

16.4.5.8.1 Function

This primitive, which is generated by the PHY PLCP sublayer, selects the power level used by the PHY for transmission.
16.4.5.8.2 Semantics of the service primitive

The primitive shall provide the following parameter:

PMD_TXPWRLVL.request(
  TXPWR_LEVEL
)

TXPWR_LEVEL selects which of the optional transmit power levels should be used for the current packet transmission. The number of available power levels shall be determined by the MIB parameter dot11NumberOfSupportedPowerLevelsImplemented. See 16.4.7.4 for further information on the optional DSSS PHY power-level-control capabilities.

16.4.5.8.3 When generated

This primitive shall be generated by the PLCP sublayer to select a specific transmit power. This primitive shall be applied prior to setting PMD_TXSTART to the transmit state.

16.4.5.8.4 Effect of receipt

PMD_TXPWRLVL immediately sets the transmit power level given by TXPWR_LEVEL.

16.4.5.9 PMD_RATE.request

16.4.5.9.1 Function

This primitive, which is generated by the PHY PLCP sublayer, selects the modulation rate that shall be used by the DSSS PHY for transmission.

16.4.5.9.2 Semantics of the service primitive

The primitive shall provide the following parameter:

PMD_RATE.request(
  RATE
)

The RATE parameter selects which of the DSSS PHY data rates shall be used for MPDU transmission. Subclause 16.4.6.5 provides further information on the DSSS PHY modulation rates. The DSSS PHY rate change capability is fully described in 16.2.

16.4.5.9.3 When generated

This primitive shall be generated by the PLCP sublayer to change or set the current DSSS PHY modulation rate used for the MPDU portion of a PPDU.

16.4.5.9.4 Effect of receipt

The receipt of PMD_RATE selects the rate that shall be used for all subsequent MPDU transmissions. This rate shall be used for transmission only. The DSSS PHY shall still be capable of receiving all the required DSSS PHY modulation rates.
16.4.5.10 PMD_RATE.indication

16.4.5.10.1 Function
This primitive, which is generated by the PMD sublayer, indicates which modulation rate was used to receive the MPDU portion of the PPDU. The modulation shall be indicated in the PSF.

16.4.5.10.2 Semantics of the service primitive
The primitive shall provide the following parameter:

PMD_RATE.indication(
    RATE
)

In receive mode, the RATE parameter informs the PLCP layer which of the DSSS PHY data rates was used to process the MPDU portion of the PPDU. Subclause 16.4.6.5 provides further information on the DSSS PHY modulation rates. The DSSS PHY rate change capability is fully described in 16.2.

16.4.5.10.3 When generated
This primitive shall be generated by the PMD sublayer when the PSF has been properly detected.

16.4.5.10.4 Effect of receipt
This parameter shall be provided to the PLCP layer for information only.

16.4.5.11 PMD_RSSI.indication

16.4.5.11.1 Function
This optional primitive, which is generated by the PMD sublayer, provides to the PLCP and MAC entity the receive signal strength.

16.4.5.11.2 Semantics of the service primitive
The primitive shall provide the following parameter:

PMD_RSSI.indication(
    RSSI
)

The RSSI shall be a measure of the RF energy received by the DSSS PHY. RSSI indications of up to 8 bits (256 levels) are supported.

16.4.5.11.3 When generated
This primitive shall be generated by the PMD when the DSSS PHY is in the receive state. It shall be continuously available to the PLCP, which, in turn, provides the parameter to the MAC entity.

16.4.5.11.4 Effect of receipt
This parameter shall be provided to the PLCP layer for information only. The RSSI may be used in conjunction with SQ as part of a CCA scheme.
16.4.5.12 PMD_SQ.indication

16.4.5.12.1 Function

This optional primitive, which is generated by the PMD sublayer, provides to the PLCP and MAC entity the SQ of the DSSS PHY PN code correlation. The SQ shall be sampled when the DSSS PHY achieves code lock and shall be held until the next code lock acquisition.

16.4.5.12.2 Semantics of the service primitive

The primitive shall provide the following parameter:

```
PMD_SQ.indication(
    SQ
)
```

The SQ shall be a measure of the PN code correlation quality received by the DSSS PHY. SQ indications of up to 8 bits (256 levels) are supported.

16.4.5.12.3 When generated

This primitive shall be generated by the PMD when the DSSS PHY is in the receive state and code lock is achieved. It shall be continuously available to the PLCP, which, in turn, provides the parameter to the MAC entity.

16.4.5.12.4 Effect of receipt

This parameter shall be provided to the PLCP layer for information only. The SQ may be used in conjunction with RSSI as part of a CCA scheme.

16.4.5.13 PMD_CS.indication

16.4.5.13.1 Function

This primitive, which is generated by the PMD, shall indicate to the PLCP layer that the receiver has acquired (locked) the PN code and data are being demodulated.

16.4.5.13.2 Semantics of the service primitive

The PMD_CS (carrier sense) primitive in conjunction with PMD_ED provides CCA status through the PLCP layer PHY-CCA primitive. PMD_CS indicates a binary status of ENABLED or DISABLED. PMD_CS shall be ENABLED when the correlator SQ indicated in PMD_SQ is greater than the CS_THRESHOLD parameter. PMD_CS shall be DISABLED when the PMD_SQ falls below the correlation threshold.

16.4.5.13.3 When generated

This primitive shall be generated by the PHY when the DSSS PHY is receiving a PPDU and the PN code has been acquired.

16.4.5.13.4 Effect of receipt

This indicator shall be provided to the PLCP for forwarding to the MAC entity for information purposes through the PHY-CCA indicator. This parameter shall indicate that the RF medium is busy and occupied by
a DSSS PHY signal. The DSSS PHY should not be placed into the transmit state when PMD_CS is ENABLED.

16.4.5.14 PMD_ED.indication

16.4.5.14.1 Function

This optional primitive, which is generated by the PMD, shall indicate to the PLCP layer that the receiver has detected RF energy indicated by the PMD_RSSI primitive that is above a predefined threshold.

16.4.5.14.2 Semantics of the service primitive

The PMD_ED (energy detect) primitive, along with the PMD_SQ, provides CCA status at the PLCP layer through the PHY-CCA primitive. PMD_ED indicates a binary status of ENABLED or DISABLED. PMD_ED shall be ENABLED when the RSSI indicated in PMD_RSSI is greater than the ED_THRESHOLD parameter. PMD_ED shall be DISABLED when the PMD_RSSI falls below the energy detect threshold.

16.4.5.14.3 When generated

This primitive shall be generated by the PHY when the PHY is receiving RF energy from any source that exceeds the ED_THRESHOLD parameter.

16.4.5.14.4 Effect of receipt

This indicator shall be provided to the PLCP for forwarding to the MAC entity for information purposes through the PMD_ED indicator. This parameter shall indicate that the RF medium may be busy with an RF energy source that is not DSSS PHY compliant. If a DSSS PHY source is being received, the PMD_CS function shall be enabled shortly after the PMD_ED function is enabled.

16.4.5.15 PMD_ED.request

16.4.5.15.1 Function

This optional primitive, which is generated by the PHY PLCP, sets the energy detect ED_THRESHOLD value.

16.4.5.15.2 Semantics of the service primitive

The primitive shall provide the following parameter:

\[
\text{PMD\_ED.request(ED\_THRESHOLD)}
\]

ED_THRESHOLD is the value that the RSSI indicated shall exceed for PMD_ED to be enabled.

16.4.5.15.3 When generated

This primitive shall be generated by the PLCP sublayer to change or set the current DSSS PHY energy detect threshold.

16.4.5.15.4 Effect of receipt

The receipt of PMD_ED immediately changes the ED threshold as set by the ED_THRESHOLD parameter.
16.4.5.16 PHY-CCA.indication

16.4.5.16.1 Function

This primitive, which is generated by the PMD, indicates to the PLCP layer that the receiver has detected RF energy that adheres to the CCA algorithm.

16.4.5.16.2 Semantics of the service primitive

The PHY-CCA primitive provides CCA status at the PLCP layer to the MAC.

16.4.5.16.3 When generated

This primitive shall be generated by the PHY when the PHY is receiving RF energy from any source that exceeds the ED_THRESHOLD parameter (PMD_ED is active), and optionally is a valid correlated DSSS PHY signal whereby PMD_CS would also be active.

16.4.5.16.4 Effect of receipt

This indicator shall be provided to the PLCP for forwarding to the MAC entity for information purposes through the PHY-CCA indicator. This parameter indicates that the RF medium may be busy with an RF energy source that may or may not be DSSS PHY compliant. If a DSSS PHY source is being received, the PMD_CS function shall be enabled shortly after the PMD_ED function is enabled.

16.4.5.17 PMD_RCPI.indication

16.4.5.17.1 Function

This optional primitive, generated by the PMD sublayer, provides the received channel power indicator (RCPI) to the PLCP and MAC.

16.4.5.17.2 Semantics of the service primitive

The primitive shall provide the following parameter:

PMD_RCPI.indication( RCPI )

The RCPI shall be a measure of the channel power received by the DSSS PHY. RCPI indications are supported as defined in 16.4.8.6.

16.4.5.17.3 When generated

This primitive shall be generated by the PMD when the DSSS PHY is in the receive state. It shall be continuously available to the PLCP, which in turn provides the parameter to the MAC entity.

16.4.5.17.4 Effect of receipt

This parameter shall be provided to the PLCP layer for information only. The RCPI may be used in conjunction with RSNI to measure input signal quality.
16.4.6 PMD operating specifications, general

16.4.6.1 General

Subclause 16.4.6 provides general specifications for the DSSS PMD sublayer. These specifications apply to both the Receive and the Transmit functions and general operation of a DSSS PHY.

16.4.6.2 Operating frequency range

The DSSS PHY shall operate in the frequency range of 2.4 GHz to 2.4835 GHz as allocated by regulatory bodies in the China, United States and Europe or in the 2.471 GHz to 2.497 GHz frequency band as allocated by regulatory authority in Japan.

16.4.6.3 Channel Numbering of operating channels

When dot11OperatingClassesRequired is true, channel numbering shall be as specified in 18.3.8.4.2 and channelization shall be as specified in 18.3.8.4.3. When dot11OperatingClassesDefined is false or not defined, the channel center frequencies and CHNL_ID numbers shall be as shown in Table 16-7. See the applicable regulations for the countries in which the implementation operates.

Table 16-7—DSSS PHY frequency channel plan

In a multiple cell network topology, overlapping and/or adjacent cells using different channels can operate simultaneously without interference if the distance between the center frequencies is at least 30 MHz. Channel 14 shall be designated specifically for operation in Japan.
16.4.6.4 Spreading sequence

The following 11-chip Barker sequence shall be used as the PN code sequence:
+1, −1, +1, +1, −1, +1, +1, −1, −1, −1

The leftmost chip shall be output first in time. The first chip shall be aligned at the start of a transmitted symbol. The symbol duration shall be exactly 11 chips long.

16.4.6.5 Modulation and channel data rates

Two modulation formats and data rates are specified for the DSSS PHY: a basic access rate and an enhanced access rate. The basic access rate shall be based on 1 Mb/s DBPSK modulation. The DBPSK encoder is specified in Table 16-8. The enhanced access rate shall be based on 2 Mb/s DQPSK. The DQPSK encoder is specified in Table 16-9. (In the tables, +jω shall be defined as counterclockwise rotation.)

16.4.6.6 Transmit and receive in-band and out-of-band spurious emissions

The DSSS PHY shall conform with in-band and out-of-band spurious emissions as set by the appropriate regulatory bodies.

16.4.6.7 TX-to-RX turnaround time

The TX-to-RX turnaround time shall be less than 10 µs, including the power-down ramp specified in 16.4.7.8.

The TX-to-RX turnaround time shall be measured at the air interface from the trailing edge of the last transmitted symbol to valid CCA detection of the incoming signal. The CCA should occur within 25 µs (10 µs for turnaround time plus 15 µs for energy detect) or by the next slot boundary occurring after 25 µs has elapsed (refer to 16.4.8.5). A receiver input signal 3 dB above the ED threshold described in 16.4.8.5 shall be present at the receiver.
16.4.6.8 RX-to-TX turnaround time

The RX-to-TX turnaround time shall be measured at the MAC/PHY interface, using the PHY-TXSTART.request primitive and shall be \( \leq 5 \mu s \). This includes the transmit power-on ramp described in 16.4.7.8.

16.4.6.9 Slot time

The slot time for the DSSS PHY shall be the sum of the RX-to-TX turnaround time (5 \( \mu s \)) and the energy detect time (15 \( \mu s \) specified in 16.4.8.5). The propagation delay shall be regarded as being included in the energy detect time.

16.4.6.10 Transmit and receive antenna port impedance

The impedance of the transmit and receive antenna port(s) shall be 50 \( \Omega \) if the port is exposed.

16.4.7 PMD transmit specifications

16.4.7.1 Introduction

The transmit functions and parameters associated with the PMD sublayer are described in 16.4.7.2 to 16.4.7.10.

16.4.7.2 Transmit power levels

The maximum allowable output power is measured in accordance with practices specified by the appropriate regulatory bodies.

16.4.7.3 Minimum transmitted power level

The minimum transmitted power shall be no less than 1 mW.

16.4.7.4 Transmit power level control

Power control shall be provided for transmitted power greater than 100 mW. A maximum of four power levels may be provided. At a minimum, a radio capable of transmission greater than 100 mW shall be capable of switching power back to 100 mW or less.

16.4.7.5 Transmit spectrum mask

The transmitted spectral products shall be less than \(-30\ \text{dBr}\) (decibel relative to the SINx/x peak) for \( f_c - 22\ \text{MHz} < f < f_c - 11\ \text{MHz} \), \( f_c + 11\ \text{MHz} < f < f_c + 22\ \text{MHz} \), \(-50\ \text{dBr}\) for \( f < f_c - 22\ \text{MHz} \), and \( f > f_c + 22\ \text{MHz} \), where \( f_c \) is the channel center frequency. The transmit spectral mask is shown in Figure 16-11. The measurements shall be made using 100 kHz resolution bandwidth and a 30 kHz video bandwidth.

Channel 14 is unique. The Japanese standard ARIB RCR-STD 33 (5.0) [B7] states that B90/2\( \pi \) normalized to the 'transmission speed of modulation signal' shall be \( \geq 10 \). Therefore, for channel 14, B90/2\( \pi \) > 13.75 MHz for CCK spreading and >10.0 MHz for Barker spreading.
16.4.7.6 Transmit center frequency tolerance

The transmitted center frequency tolerance shall be ±25 ppm maximum.

16.4.7.7 Chip clock frequency tolerance

The PN code chip clock frequency tolerance shall be better than ±25 ppm maximum.

16.4.7.8 Transmit power-on and power-down ramp

The transmit power-on ramp for 10% to 90% of maximum power shall be no greater than 2 µs. The transmit power-on ramp is shown in Figure 16-12.

The transmit power-down ramp for 90% to 10% maximum power shall be no greater than 2 µs. The transmit power-down ramp is shown in Figure 16-13.

The transmit power ramps shall be constructed such that the DSSS PHY emissions conform with the spurious frequency product specification defined in 16.4.6.6.
16.4.7.9 RF carrier suppression

The RF carrier suppression, measured at the channel center frequency, shall be at least 15 dB below the peak SIN(x)/x power spectrum. The RF carrier suppression shall be measured while transmitting a repetitive 01 data sequence with the scrambler disabled using DQPSK modulation. A 100 kHz resolution bandwidth shall be used to perform this measurement.

16.4.7.10 Transmit modulation accuracy

The transmit modulation accuracy requirement for the DSSS PHY shall be based on the difference between the actual transmitted waveform and the ideal signal waveform. Modulation accuracy shall be determined by measuring the peak vector error magnitude measured during each chip period. Worst-case vector error magnitude shall not exceed 0.35 for the normalized sampled chip data. The ideal complex I and Q constellation points associated with DQPSK modulation (0.707, 0.707), (0.707, –0.707), (–0.707, 0.707), (–0.707, –0.707) shall be used as the reference. These measurements shall be from baseband I and Q sampled data after recovery through a reference receiver system.

Figure 16-14 illustrates the ideal DQPSK constellation points and range of worst-case error specified for modulation accuracy.
Error vector measurement requires a reference receiver capable of carrier lock. All measurements shall be made under carrier lock conditions. The distortion induced in the constellation by the reference receiver shall be calibrated and measured. The test data error vectors described below shall be corrected to compensate for the reference receiver distortion.

The IEEE 802.11 vendor compatible radio shall provide an exposed TX chip clock, which shall be used to sample the I and Q outputs of the reference receiver.

The measurement shall be made under the conditions of continuous DQPSK transmission using scrambled all ones.

The eye pattern of the I channel shall be used to determine the I and Q sampling point. The chip clock provided by the vendor radio shall be time delayed such that the samples fall at a 1/2 chip period offset from the mean of the zero crossing positions of the eye (see Figure 16-15). This is the ideal center of the eye and may not be the point of maximum eye opening.

![Figure 16-15—Chip clock alignment with baseband eye pattern](image)

Using the aligned chip clock, 1000 samples of the I and Q baseband outputs from the reference receiver are captured. The vector error magnitudes shall be calculated as follows:

Calculate the dc offsets for I and Q samples.

\[
I_{\text{mean}} = \frac{1000}{n=1} \sum I(n) / 1000
\]

\[
Q_{\text{mean}} = \frac{1000}{n=1} \sum Q(n) / 1000
\]

Calculate the dc corrected I and Q samples for all \( n = 1000 \) sample pairs.

\[
I_{\text{dc}}(n) = I(n) - I_{\text{mean}}
\]
\[ Q_{dc}(n) = Q(n) - Q_{\text{mean}} \]

Calculate the average magnitude of \( I \) and \( Q \) samples.

\[
I_{\text{mag}} = \frac{\sum_{n=1}^{1000} |I_{dc}(n)|}{1000}
\]

\[
Q_{\text{mag}} = \frac{\sum_{n=1}^{1000} |Q_{dc}(n)|}{1000}
\]

Calculate the normalized error vector magnitude for the \( I_{dc}(n)/Q_{dc}(n) \) pairs.

\[
V_{\text{err}}(n) = \left( \frac{|I_{dc}(n)|}{I_{\text{mag}}} - 1 \right)^2 + \left( \frac{|Q_{dc}(n)|}{Q_{\text{mag}}} - 1 \right)^2 - V_{\text{correction}}
\]

with \( V_{\text{correction}} = \) error induced by the reference receiver system.

A vendor DSSS PHY implementation shall be compliant if for all \( n = 1000 \) samples the following condition is met:

\[
V_{\text{err}}(n) < 0.35
\]

16.4.7.11 Time of Departure accuracy

The Time of Departure accuracy test evaluates TIME_OF_DEPARTURE against aTxPmdTxStartRMS and aTxPmdTxStartRMS against TIME_OF_DEPART URE_ACCURACY_TEST_THRESH as defined Annex T with the following test parameters:

- MULTICHANNEL_SAMPLING_RATE is \( 22 \times 10^6 \left( 1 + \left[ \frac{f_H - f_L}{22 \text{ MHz}} \right] \right) \) sample/s

where

- \( f_H \) is the nominal center frequency in Hz of the highest channel in the channel set
- \( f_L \) is the nominal center frequency in Hz of the lowest channel in the channel set, the channel set is the set of channels upon which frames providing measurements are transmitted, the channel set comprises channels uniformly spaced across \( f_H - f_L \geq 50 \text{ MHz} \)

\([x]\) equals the smallest integer equal to or larger than \( x \)

- FIRST_TRANSITION_FIELD is the SYNC field.
- SECOND_TRANSITION_FIELD is the SFD field.
- TRAINING_FIELD is the concatenation of the SYNC and SFD fields, using a chip pulse that should approximate a rectangular pulse of duration 1/11 MHz convolved with a brick-wall low pass filter of bandwidth 11 MHz.
- TIME_OF_DEPARTURE_ACCURACY_TEST_THRESH is 80 ns.

NOTE—The indicated chip pulse applies to the time of departure accuracy test equipment, and not the transmitter or receiver.
16.4.8 PMD receiver specifications

16.4.8.1 Introduction

The receive functions and parameters associated with the PMD sublayer are described in 16.4.8.2 to 16.4.8.5.

16.4.8.2 Receiver minimum input level sensitivity

The FER shall be less than $8 \times 10^{-2}$ at an MPDU length of 1024 octets for an input level of –80 dBm measured at the antenna connector. This FER shall be specified for 2 Mb/s DQPSK modulation. The test for the minimum input level sensitivity shall be conducted with the ED threshold set $\leq$ –80 dBm.

16.4.8.3 Receiver maximum input level

The receiver shall provide a maximum FER of $8 \times 10^{-2}$ at an MPDU length of 1024 octets for a maximum input level of –4 dBm measured at the antenna. This FER shall be specified for 2 Mb/s DQPSK modulation.

16.4.8.4 Receiver adjacent channel rejection

Adjacent channel rejection is defined between any two channels with $\geq 30$ MHz separation in each channel group defined in 16.4.6.3.

The adjacent channel rejection shall be $\geq 35$ dB with an FER of $8 \times 10^{-2}$ using 2 Mb/s DQPSK modulation described in 16.4.6.5 and an MPDU length of 1024 octets.

The adjacent channel rejection shall be measured using the following method:

Input a 2 Mb/s DQPSK modulated signal at a level 6 dB greater than specified in 16.4.8.2. In an adjacent channel ($\geq 30$ MHz separation as defined by the channel numbering), input a signal modulated in a similar fashion that adheres to the transmit mask specified in 16.4.7.5 to a level 41 dB above the level specified in 16.4.8.2. The adjacent channel signal shall be derived from a separate signal source. It shall not be a frequency shifted version of the reference channel. Under these conditions, the FER shall be no worse than $8 \times 10^{-2}$.

16.4.8.5 CCA

The DSSS PHY shall provide the capability to perform CCA according to at least one of the following three methods:

— **CCA Mode 1**: Energy above threshold. CCA shall report a busy medium upon detection of any energy above the ED threshold.

— **CCA Mode 2**: CS only. CCA shall report a busy medium only upon detection of a DSSS signal. This signal may be above or below the ED threshold.

— **CCA Mode 3**: CS with energy above threshold. CCA shall report a busy medium upon detection of a DSSS signal with energy above the ED threshold.

The ED status shall be given by the PMD primitive, PMD_ED. The CS status shall be given by PMD_CS. The status of PMD_ED and PMD_CS is used in the PLCP to indicate activity to the MAC through the PHY PHY-CCA.indication primitive.

A busy channel shall be indicated by a PHY-CCA.indication primitive of class BUSY.

A clear channel shall be indicated by a PHY-CCA.indication primitive of class IDLE.
The dot11CCAModeSupported shall indicate the appropriate operation modes. The PHY shall be configured through dot11CurrentCCAMode.

The CCA shall be true if there is no energy detect or CS. The CCA parameters are subject to the following criteria:

a) The ED threshold shall be $\leq -80$ dBm for TX power $> 100$ mW, $-76$ dBm for $50$ mW $< $ TX power $\leq 100$ mW, and $-70$ dBm for TX power $\leq 50$ mW.

b) With a valid signal (according to the CCA mode of operation) present at the receiver antenna within 5 µs of the start of a MAC slot boundary, the CCA indicator shall report channel busy before the end of the slot time. This implies that the CCA signal is available as an exposed test point. Refer to Figure 9-14 (in 9.3.7) for a definition of slot time boundary.

c) In the event that a correct PLCP header is received, the DSSS PHY shall hold the CCA signal inactive (channel busy) for the full duration as indicated by the PLCP LENGTH field. Should a loss of CS occur in the middle of reception, the CCA shall indicate a busy medium for the intended duration of the transmitted packet.

Conformance to DSSS PHY CCA shall be demonstrated by applying a DSSS-compliant signal, above the appropriate ED threshold (item a), so that all conditions described in item b and item c are demonstrated.

16.4.8.6 Received Channel Power Indicator Measurement

The RCPI indicator is a measure of the received RF power in the selected channel for a received frame. This parameter shall be a measure by the PHY sublayer of the received RF power in the channel measured over the entire received frame or by other equivalent means that meet the specified accuracy. RCPI shall be a monotonically increasing, logarithmic function of the received power level defined in dBm. The allowed values for the RCPI parameter shall be an 8-bit value in the range from 0 to 220, with indicated values rounded to the nearest 0.5 dB as follows:

0: Power $\leq -110$ dBm

1: Power $= -109.5$ dBm

2: Power $= -109.0$ dBm

and so on where

$$\text{RCPI} = \text{Int}\{(\text{Power in dBm} + 110) \times 2\} \text{ for } 0 \text{ dBm} > \text{Power} > -110 \text{ dBm}$$

220: Power $\geq 0$ dBm

221–254: Reserved

255: Measurement not available

RCPI shall equal the received RF power within an accuracy of $\pm 5$ dB (95% confidence interval) within the specified dynamic range of the receiver. The received RF power shall be determined assuming a receiver noise equivalent bandwidth equal to the channel bandwidth multiplied by 1.1.
17. High Rate direct sequence spread spectrum (HR/DSSS) PHY specification

17.1 Overview

17.1.1 General

This clause specifies the High Rate extension of the PHY for the DSSS system (see Clause 16), hereinafter known as the High Rate PHY for the 2.4 GHz band designated for ISM applications.

This extension of the DSSS system builds on the data rate capabilities, as described in Clause 16, to provide 5.5 Mb/s and 11 Mb/s payload data rates in addition to the 1 Mb/s and 2 Mb/s rates. To provide the higher rates, 8-chip complementary code keying (CCK) is employed as the modulation scheme. The chipping rate is 11 MHz, which is the same as the DSSS system described in Clause 16, thus providing the same occupied channel bandwidth. The basic new capability described in this clause is called HR/DSSS. The basic High Rate PHY uses the same PLCP preamble and header as the DSSS PHY, so both PHYs can co-exist in the same BSS and can use the rate switching mechanism as provided.

In addition to providing higher speed extensions to the DSSS system, a number of optional features allow the performance of the RF LAN system to be improved as technology allows the implementation of these options to become cost effective.

An optional mode replacing the CCK modulation with HR/DSSS/PBCC is provided.

The PBCC option is obsolete. Consequently, this option may be removed in a later revision of the standard.

Another optional mode is provided that allows data throughput at the higher rates (2, 5.5, and 11 Mb/s) to be significantly increased by using a shorter PLCP preamble. This mode is called HR/DSSS/short, or HR/DSSS/PBCC/short. This short preamble mode can coexist with DSSS, HR/DSSS, or HR/DSSS/PBCC under limited circumstances, such as on different channels or with appropriate CCA mechanisms.

An optional capability for Channel Agility is also provided. This option allows an implementation to overcome some inherent difficulty with static channel assignments (a tone jammer), without burdening all implementations with the added cost of this capability. This option can also be used to implement IEEE 802.11-compliant systems that are interoperable with both FH and DS modulations. See Annex K for more details.

17.1.2 Scope

This clause specifies the PHY entity for the HR/DSSS extension and explains how this standard accommodates the High Rate PHY.

The High Rate PHY consists of the following two protocol functions:

a) A PHY convergence function, which adapts the capabilities of the PMD system to the PHY service. This function is supported by the PLCP, which defines a method for mapping the MPDUs into a framing format suitable for sending and receiving user data and management information between two or more STAs using the associated PMD system. The PHY exchanges PPDUs that contain PSDUs. The MAC uses the PHY service, so each MPDU corresponds to a PSDU that is carried in a PPDU.

b) A PMD system, whose function defines the characteristics of, and method of transmitting and receiving data through, a WM between two or more STAs, each using the High Rate PHY system.
17.1.3 High Rate PHY functions

17.1.3.1 General

The 2.4 GHz High Rate PHY architecture is depicted in the ISO/IEC basic reference model shown in Figure 17-10 (in 17.4.1). The High Rate PHY contains three functional entities: the PMD function, the PHY convergence function, and the layer management function. Each of these functions is described in detail in 17.1.3.2, 17.1.3.3, and 17.1.3.4. For the purposes of MAC and MAC management, when Channel Agility is both present and enabled (see 17.3.2 and Annex J), the High Rate PHY shall be interpreted to be both a High Rate and an FH PHY.

The High Rate PHY service shall be provided to the MAC through the PHY service primitives described in Clause 7.

17.1.3.2 PLCP sublayer

To allow the MAC to operate with minimum dependence on the PMD sublayer, a PLCP sublayer is defined. This function simplifies the PHY service interface to the MAC services.

17.1.3.3 PMD sublayer

The PMD sublayer provides a means and method of transmitting and receiving data through a WM between two or more STAs, each using the High Rate system.

17.1.3.4 PLME

The PLME performs management of the local PHY functions in conjunction with the MLME.

17.1.4 Service specification method and notation

The models represented by figures and state diagrams are intended to be illustrations of functions provided. It is important to distinguish between a model and a real implementation. The models are optimized for simplicity and clarity of presentation; the actual method of implementation is left to the discretion of the High-Rate-PHY-compliant developer.

The service of a layer or sublayer is a set of capabilities that it offers to a user in the next-higher layer (or sublayer). Abstract services are specified here by describing the service primitives and parameters that characterize each service. This definition is independent of any particular implementation.

17.2 High Rate PLCP sublayer

17.2.1 Overview

Subclause 17.2 provides a convergence procedure for the 2 Mb/s, 5.5 Mb/s, and 11 Mb/s specification, in which PSDUs are converted to and from PPDUs. During transmission, the PSDU shall be appended to a PLCP preamble and header to create the PPDU. Two different preambles and headers are defined: the mandatory supported long preamble and header, which interoperates with the current 1 Mb/s and 2 Mb/s DSSS specification, and an optional short preamble and header. At the receiver, the PLCP preamble and header are processed to aid in demodulation and delivery of the PSDU.

The optional short preamble and header is intended for applications where maximum throughput is desired and interoperability with legacy and nonshort-preamble-capable equipment is not a consideration. That is, it is expected to be used only in networks of like equipment, which can all handle the optional mode.
17.2.2 PPDU format

17.2.2.1 General

Two different preambles and headers are defined: the mandatory supported long preamble and header, which is interoperable with the current 1 Mb/s and 2 Mb/s DSSS specification, and an optional short preamble and header.

17.2.2.2 Long PPDU format

Figure 17-1 shows the format for the interoperable (long) PPDU, including the High Rate PLCP preamble, the High Rate PLCP header, and the PSDU. The PLCP preamble contains the following fields: SYNC and SFD. The PLCP header contains the following fields: signaling (SIGNAL), service (SERVICE), length (LENGTH), and CRC-16. Each of these fields is described in detail in 17.2.3. The format for the PPDU, including the long High Rate PLCP preamble, the long High Rate PLCP header, and the PSDU, does not differ from the format for 1 Mb/s and 2 Mb/s. The only exceptions are:

a) The encoding of the rate in the SIGNAL field;
b) The use of a bit in the SERVICE field to resolve an ambiguity in PSDU length in octets, when the length is expressed in whole microseconds;
c) The use of a bit in the SERVICE field to indicate if the optional PBCC mode is being used;
d) The use of a bit in the SERVICE field to indicate that the transit frequency and bit clocks are locked.

17.2.2.3 Short PPDU format

The short PLCP preamble and header (HR/DSSS/short) is defined as optional for HR/DSSS. The short preamble and header may be used to minimize overhead and, thus, maximize the network data throughput. The format of the PPDU, with HR/DSSS/short, is depicted in Figure 17-2. For Clause 19 STAs support of this preamble type is mandatory.

A transmitter using the short PLCP is only interoperable with another receiver that is also capable of receiving this short PLCP. To interoperate with a receiver that is not capable of receiving a short preamble and header, the transmitter shall use the long PLCP preamble and header. The short PLCP preamble uses the 1 Mb/s Barker code spreading with DBPSK modulation. The short PLCP header uses the 2 Mb/s Barker code spreading with DQPSK modulation, and the PSDU is transmitted at 2 Mb/s, 5.5 Mb/s, or 11 Mb/s.
17.2.3 PPDU field definitions

17.2.3.1 General

In the PLCP field definition subclauses (17.2.3.2 to 17.2.3.15), the definitions of the long (Clause 16) PLCP fields are given first, followed by the definitions of the short PLCP. The names for the short PLCP fields are preceded by the term short.

17.2.3.2 Long PLCP SYNC field

The SYNC field shall consist of 128 bits of scrambled 1 bits. This field is provided so the receiver can perform the necessary synchronization operations. The initial state of the scrambler (seed) shall be [1101100], where the leftmost bit specifies the value to put in the first delay element (Z1) in Figure 17-5 (in 17.2.4), and the rightmost bit specifies the value to put in the last delay element in the scrambler.

To support the reception of DSSS signals generated with implementations based on Clause 16, the receiver shall also be capable of synchronization on a SYNC field derived from any nonzero scrambler initial state.

17.2.3.3 Long PLCP SFD

The SFD shall be provided to indicate the start of PHY-dependent parameters within the PLCP preamble. The SFD shall be a 16-bit field, [1111 0011 1010 0000], where the rightmost bit shall be transmitted first in time.

17.2.3.4 Long PLCP SIGNAL field

The 8-bit SIGNAL field indicates to the PHY the modulation that shall be used for transmission (and reception) of the PSDU. The data rate shall be equal to the SIGNAL field value multiplied by 100 kbit/s. The High Rate PHY supports four mandatory rates given by the following 8-bit words, which represent the rate in units of 100 kbit/s, where the LSB shall be transmitted first in time:

a) X’0A’ (MSB to LSB) for 1 Mb/s;
b) X’14’ (MSB to LSB) for 2 Mb/s;
c) X’37’ (MSB to LSB) for 5.5 Mb/s;

Figure 17-2—Short PPDU format
d) X’6E’ (MSB to LSB) for 11 Mb/s.

The High Rate PHY rate change capability is described in 17.2.3.15. This field shall be protected by the CRC-16 FCS described in 17.2.3.7.

17.2.3.5 Long PLCP SERVICE field

Three bits have been defined in the SERVICE field to support the High Rate extension. The rightmost bit (bit 7) shall be used to supplement the LENGTH field described in 17.2.3.6. Bit 3 shall be used to indicate whether the modulation method is CCK <0> or PBCC <1>, as shown in Table 17-1. Bit 2 shall be used to indicate that the transmit frequency and symbol clocks are derived from the same oscillator. This locked clocks bit shall be set by the PHY based on its implementation configuration. The SERVICE field shall be transmitted b0 first in time, and shall be protected by the CRC-16 FCS described in 17.2.3.7. An IEEE 802.11-compliant device shall set the values of the bits b0, b1, b4, b5, and b6 to 0.

Table 17-1—SERVICE field definitions

17.2.3.6 Long PLCP LENGTH field

The PLCP LENGTH field shall be an unsigned 16-bit integer that indicates the number of microseconds required to transmit the PSDU. The transmitted value shall be determined from the LENGTH and DATARATE parameters in the TXVECTOR issued with the PHY-TXSTART.request primitive described in 17.4.4.3.

The LENGTH field provided in the TXVECTOR is in octets and is converted to microseconds for inclusion in the PLCP LENGTH field. The LENGTH field is calculated as follows. Because there is an ambiguity in the number of octets that is described by a length in integer microseconds for any data rate over 8 Mb/s, a length extension bit shall be placed at bit position b7 in the SERVICE field to indicate when the smaller potential number of octets is correct as follows:

a) 5.5 Mb/s CCK  
Length = number of octets × 8/5.5, rounded up to the next integer.

b) 11 Mb/s CCK  
Length = number of octets × 8/11, rounded up to the next integer; the service field (b7) bit shall indicate a 0 if the rounding took less than 8/11 or a 1 if the rounding took more than or equal to 8/11.

c) 5.5 Mb/s PBCC  
Length = (number of octets + 1) × 8/5.5, rounded up to the next integer.

d) 11 Mb/s PBCC  
Length = (number of octets + 1) × 8/11, rounded up to the next integer; the service field (b7) bit shall indicate a 0 if the rounding took less than 8/11 or a 1 if the rounding took more than or equal to 8/11.

At the receiver, the number of octets in the MPDU is calculated as follows:

a) 5.5 Mb/s CCK  
Number of octets = Length × 5.5/8, rounded down to the next integer.

b) 11 Mb/s CCK  
Number of octets = Length × 11/8, rounded down to the next integer, minus 1 if the service field (b7) bit is a 1.

c) 5.5 Mb/s PBCC  
Number of octets = (Length × 5.5/8) − 1, rounded down to the next integer.
d) 11 Mb/s PBCC  Number of octets = \((\text{Length} \times 11/8) – 1\), rounded down to the next integer, minus 1 if the service field (b7) bit is a 1.

An example for an 11 Mb/s calculation described in pseudocode form is shown below. At the transmitter, the values of the LENGTH field and length extension bit are calculated as follows:

\[
\text{LENGTH}' = ((\text{number of octets} + P) \times 8) / R
\]

\[
\text{LENGTH} = \text{Ceiling (LENGTH')}
\]

If

\[(R = 11) \text{ and } ((\text{LENGTH}–\text{LENGTH}') \geq 8/11)\]

then

Length Extension = 1

else

Length Extension = 0

where

- \(R\) is the data rate (Mb/s)
- \(P\) is 0 for CCK
- \(P\) is 1 for PBCC

\(\text{Ceiling (X)}\) returns the smallest integer value greater than or equal to \(X\)

At the receiver, the number of octets in the MPDU is calculated as follows:

\[
\text{Number of octets} = \text{Floor}(((\text{Length} \times R) / 8) – P) – \text{Length Extension}
\]

where

- \(R\) is the data rate (Mb/s)
- \(P\) is 0 for CCK
- \(P\) is 1 for PBCC

\(\text{Floor (X)}\) returns the largest integer value less than or equal to \(X\)

Table 17-2 shows an example calculation for several packet lengths of CCK at 11 Mb/s.

</tbody>
</table>

This example illustrates why normal rounding or truncation of the number does produce the right result. The LENGTH field is defined in units of microseconds and corresponds to the actual length, and the number of octets is exact.

The LSB shall be transmitted first in time. This field shall be protected by the CRC-16 FCS described in 17.2.3.7.

17.2.3.7 PLCP CRC (CRC-16) field

The SIGNAL, SERVICE, and LENGTH fields shall be protected with a CRC-16 FCS. The CRC-16 FCS shall be the ones complement of the remainder generated by the modulo 2 division of the protected PLCP fields by the polynomial

\[ x^{16} + x^{12} + x^5 + 1 \]

The protected bits shall be processed in transmit order. All FCS calculations shall be made prior to data scrambling. A schematic of the processing is shown in Figure 17-3.

As an example, the SIGNAL, SERVICE, and LENGTH fields for a DBPSK signal with a PPDU length of 192 μs (24 octets) would be given by the following:

0101 0000 0000 0000 0000 0111 0000 0000 [leftmost bit (b0) transmitted first in time]

b0..................................................b48

The ones complement FCS for these protected PLCP preamble bits would be the following:

0101 1011 0101 0111 [leftmost bit (b0) transmitted first in time]

b0..........................b16

Figure 17-3 depicts this example.

An illustrative example of the CRC-16 FCS using the information from Figure 17-3 is shown in Figure 17-4.
Figure 17-3—CRC-16 implementation
17.2.3.8 Long PLCP data modulation and modulation rate change

The long PLCP preamble and header shall be transmitted using the 1 Mb/s DBPSK modulation. The SIGNAL and SERVICE fields combined shall indicate the modulation that shall be used to transmit the PSDU. The SIGNAL field indicates the rate, and the SERVICE field indicates the modulation. The transmitter and receiver shall initiate the modulation and rate indicated by the SIGNAL and SERVICE fields, starting with the first octet of the PSDU. The PSDU transmission rate shall be set by the DATARATE parameter in the TXVECTOR, issued with the PHY-TXSTART.request primitive described in 17.4.4.2.

17.2.3.9 Short PLCP synchronization (shortSYNC)

The shortSYNC field shall consist of 56 bits of scrambled 0 bits. This field is provided so the receiver can perform the necessary synchronization operations. The initial state of the scrambler (seed) shall be [001 1011], where the left end bit specifies the value to place in the first delay element ($Z^1$) in Figure 17-5 (in 17.2.4), and the right end bit specifies the value to place in the last delay element ($Z^7$).

17.2.3.10 Short PLCP SFD field (shortSFD)

The shortSFD shall be a 16-bit field and be the time reverse of the field of the SFD in the long PLCP preamble (17.2.3.3). The field is the bit pattern 0000 0101 1100 1111. The right end bit shall be transmitted first in time. A receiver not configured to use the short header option does not detect this SFD.

---

</table>

; ones complement, result = CRC FCS parity
17.2.3.11 Short PLCP SIGNAL field (shortSIGNAL)

The 8-bit SIGNAL field of the short header indicates to the PHY the data rate that shall be used for transmission (and reception) of the PSDU. A PHY operating with the HR/DSSS/short option supports three mandatory rates given by the following 8-bit words, where the LSB shall be transmitted first in time and the number represents the rate in units of 100 kBit/s:

a) X’14’ (MSB to LSB) for 2 Mb/s;
b) X’37’ (MSB to LSB) for 5.5 Mb/s;
c) X’6E’ (MSB to LSB) for 11 Mb/s.

17.2.3.12 Short PLCP SERVICE field (shortSERVICE)

The SERVICE field in the short header shall be the same as the SERVICE field described in 17.2.3.5.

17.2.3.13 Short PLCP LENGTH field (shortLENGTH)

The LENGTH field in the short header shall be the same as the LENGTH field described in 17.2.3.6.

17.2.3.14 Short CRC-16 field (shortCRC)

The CRC in the short header shall be the same as the CRC field defined in 17.2.3.7. The CRC-16 is calculated over the shortSIGNAL, shortSERVICE, and shortLENGTH fields.

17.2.3.15 Short PLCP data modulation and modulation rate change

The short PLCP preamble shall be transmitted using the 1 Mb/s DBPSK modulation. The short PLCP header shall be transmitted using the 2 Mb/s modulation. The SIGNAL and SERVICE fields combined shall indicate the modulation that shall be used to transmit the PSDU. The SIGNAL field indicates the rate, and the SERVICE field indicates the modulation. The transmitter and receiver shall initiate the modulation and rate indicated by the SIGNAL and SERVICE fields, starting with the first octet of the PSDU. The PSDU transmission rate shall be set by the DATARATE parameter in the TXVECTOR, issued with the PHY-TXSTART.request primitive described in 17.4.4.2.

17.2.4 PLCP/High Rate PHY data scrambler and descrambler

The polynomial G(z) = z^{-7} + z^{-4} + 1 shall be used to scramble all bits transmitted. The feedthrough configuration of the scrambler and descrambler is self-synchronizing, which requires no prior knowledge of the transmitter initialization of the scrambler for receive processing. Figure 17-5 and Figure 17-6 show typical implementations of the data scrambler and descrambler, but other implementations are possible.
The scrambler shall be initialized as specified in 17.2.3.9 for the short PLCP and 17.2.3.2 for the long PLCP. For a long preamble, this shall result in the scrambler registers $Z^1$ to $Z^7$ in Figure 17-5 having the data pattern [1101100] (i.e., $Z^1=1...Z^7=0$) when the scrambler is first started. The scrambler shall be initialized with the reverse pattern [0011011] when transmitting the optional short preamble.

![Figure 17-6—Data descrambler](image)

**17.2.5 Transmit PLCP**

The transmit procedures for a High Rate PHY using the long PLCP preamble and header are the same as the transmit procedures described in 16.2.6 and 16.2.7 and do not change apart from the ability to transmit 5.5 Mb/s and 11 Mb/s.

The procedures for a transmitter employing HR/DSSS/short and HR/DSSS/PBCC/short are the same except for length and rate changes. The decision to use a long or short PLCP is beyond the scope of this standard.

A PHY-TXSTART.request(TXVECTOR) primitive is issued by the MAC to start the transmission of a PPDU. In addition to parameters DATARATE and LENGTH, other transmit parameters such as PREAMBLE_TYPE and MODULATION are set via the PHY-SAP with the PHY-TXSTART.request(TXVECTOR) primitive, as described in 17.3.5. The SIGNAL, SERVICE, and LENGTH fields of the PLCP header are calculated as described in 17.2.3.

The PLCP shall issue PMD_ANTSEL, PMD_RATE, and PMD_TXPWRLVL primitives to configure the PHY. The PLCP shall then issue a PMD_TXSTART.request primitive, and the PHY entity shall immediately initiate data scrambling and transmission of the PLCP preamble based on the parameters passed in the PHY-TXSTART.request primitive. The time required for transmit power-on ramp, described in 17.4.7.7, shall be included in the PLCP SYNC field. If dot11MgmtOptionTODImplemented and dot11MgmtOptionTODActivated are true or if dot11MgmtOptionTimingMsmtActivated is true and the TXVECTOR parameter TIME_OF_DEPARTURE_REQUESTED is true, then the PLCP shall issue a PHY_TXSTART.confirm(TXSTATUS) primitive to the MAC, forwarding the TIME_OF_DEPARTURE corresponding to the time when the first frame energy is sent by the transmitting port and TIME_OF_DEPARTURE_ClockRate parameter within the TXSTATUS vector. If dot11MgmtOptionTimingMsmtActivated is true, then the PLCP shall forward the value of TX_START_OF_FRAME_OFFSET in TXSTATUS vector. Once the PLCP preamble transmission is complete, data shall be exchanged between the MAC and the PHY by a series of PHY-DATA.request(DATA) primitives issued by the MAC and PHY-DATA.confirm primitives issued by the PHY. The modulation and rate change, if any, shall be initiated with the first data symbol of the PSDU, as...
described in 17.2.3.8 and 17.2.3.15. The PHY proceeds with PSDU transmission through a series of data octet transfers from the MAC. At the PMD layer, the data octets are sent in LSB-to-MSB order and presented to the PHY through PMD_DATA.request primitives. Transmission can be prematurely terminated by the MAC through the PHY-TXEND.request primitive. PHY-TXSTART shall be disabled by the issuance of the PHY-TXEND.request primitive. Normal termination occurs after the transmission of the final bit of the last PSDU octet, calculated from the number supplied in the PHY preamble LENGTH and SERVICE fields using the equations specified in 17.2.3.6. The PPDU transmission shall be completed and the PHY entity shall enter the receive state (i.e., PHY-TXSTART shall be disabled). It is recommended that modulation continue during power-down to prevent radiating a continuous wave carrier. Each PHY-TXEND.request primitive is acknowledged with a PHY-TXEND.confirm primitive from the PHY.

![Figure 17-7—Transmit PLCP](image-url)
17.2.6 Receive PLCP

The receive procedures for receivers configured to receive the mandatory and optional PLCPs, rates, and modulations are described in this subclause. A receiver that supports this High Rate extension of the standard is capable of receiving 5.5 Mb/s and 11 Mb/s, in addition to 1 Mb/s and 2 Mb/s. If the PHY implements the short preamble option, it shall detect both short and long preamble formats and indicate which type of preamble was received in the RXVECTOR. If the PHY implements the PBCC modulation option, it shall detect either CCK or PBCC modulations, as indicated in the SIGNAL field, and shall report the type of modulation used in the RXVECTOR.

The receiver shall implement the CCA procedure as defined in 17.4.8.5. Upon receiving a PPDU, the receiver shall distinguish between a long and short header format by the value of the SFD, as specified in 17.2.2. The receiver shall demodulate a long PLCP header using BPSK at 1 Mb/s. The receiver shall demodulate a short PLCP header using QPSK at 2 Mb/s. The receiver shall use the SIGNAL and SERVICE fields of the PLCP header to determine the data rate and modulation of the PSDU.

The receive PLCP is shown in Figure 17-8. In order to receive data, the PHY-TXSTART.request primitive shall be disabled so that the PHY entity is in the receive state. Further, through station management via the PLME, the PHY shall be set to the appropriate channel and the CCA method chosen. Other receive parameters, such as RSSI, RCPI, SQ, and indicated DATARATE, may be accessed via the PHY-SAP.

Upon receiving the transmitted energy, according to the selected CCA mode, the PMD_ED shall be enabled (according to 17.4.8.5) as the RSSI reaches the ED_THRESHOLD, and/or PMD_CS shall be enabled after code lock is established. These conditions are used to indicate activity to the MAC via the PHY-CCA.indication primitive, according to 17.4.8.5. A PHY-CCA.indication(BUSY) primitive shall be issued for ED and/or code lock prior to correct reception of the PLCP header. The PMD primitives, PMD_SQ, PMD_RSSI, and PMD_RCPI are issued to update the SQ, RSSI, and RCPI parameters reported to the MAC.

After a PHY-CCA.indication primitive is issued, the PHY entity shall begin searching for the SFD field. Once the SFD field is detected, CRC-16 processing shall be initiated and the PLCP SIGNAL, SERVICE, and LENGTH fields shall be received. The CRC-16 FCS shall be processed. If the CRC-16 FCS check fails, the PHY receiver shall return to the RX IDLE state, as depicted in Figure 17-9. Should the status of CCA return to the IDLE state during reception prior to completion of the full PLCP processing, the PHY receiver shall return to the RX IDLE state.

If the PLCP header reception is successful (and the SIGNAL field is completely recognizable and supported), a PHY-RXSTART.indication(RXVECTOR) primitive shall be issued. The RXVECTOR associated with this primitive includes:

a) The SIGNAL field
b) The SERVICE field
c) The PSDU length in octets (calculated from the LENGTH field in microseconds and the DATARATE in Mb/s, in accordance with the formula in 17.2.3.6)
d) RXPREAMBLE_TYPE (which is an enumerated type taking on values SHORTPREAMBLE or LONGPREAMBLE)
e) ANT_STATE (the antenna used for receive), RSSI, RCPI, and SQ
If dot11MgmtOptionTimingMsmtActivated is true, the PLCP shall do the following:

— Complete receiving the PLCP header and verify the validity of the PLCP Header.
— If the PLCP header reception is successful (and the SIGNAL field is completely recognizable and supported), a PHY-RXSTART.indication(RXVECTOR) shall be issued and RX_START_OF_FRAME_OFFSET parameter within the RXVECTOR shall be forwarded (see 17.3.5).

NOTE—The RX_START_OF_FRAME_OFFSET value is used as described in 6.3.57 in order to estimate when the start of the preamble for the incoming frame was detected on the medium at the receive antenna port.

The received PSDU bits are assembled into octets and presented to the MAC using a series of PHY-DATA.indication(DATA) primitive exchanges. The rate and modulation change indicated in the SIGNAL field shall be initiated with the first symbol of the PSDU, as described in 17.2.5. The PHY proceeds with PSDU reception. After reception of the final bit of the last PSDU octet, indicated by the PLCP preamble LENGTH field, the receiver shall be returned to the RX IDLE state shown in Figure 17-9.
A PHY-RXEND.indication(NoError) primitive shall be issued. A PHY-CCA.indication(IDLE) primitive shall be issued following a change in PHYCS and/or PHYED according to the selected CCA method.

In the event that a change in PHYCS or PHYED would cause the status of CCA to return to the IDLE state before the complete reception of the PSDU, as indicated by the PLCP LENGTH field, the error condition shall be reported to the MAC using a PHY-RXEND.indication(CarrierLost) primitive. The High Rate PHY shall ensure that the CCA indicates a busy medium for the intended duration of the transmitted PPDU.

If the PLCP header is successful, but the indicated rate or modulation in the SIGNAL and SERVICE fields is not within the capabilities of the receiver, a PHY-RXSTART.indication primitive shall not be issued. The PHY shall indicate the error condition using a PHY-RXEND.indication(UnsupportedRate) primitive. If the PLCP header is invalid, a PHY-RXSTART.indication primitive shall not be issued, and the PHY shall indicate the error condition using a PHY-RXEND.indication(FormatViolation) primitive. Also, in both
cases, the High Rate PHY shall ensure that the CCA indicates a busy medium for the intended duration of
the transmitted PSDU, as indicated by the LENGTH field. The intended duration is indicated by the
LENGTH field (LENGTH \times 1 \mu s).

A typical state machine implementation of the receive PLCP is shown in Figure 17-9.

17.3 High Rate PLME

17.3.1 PLME_SAP sublayer management primitives

Table 17-4 lists the MIB attributes that may be accessed by the PHY entities and intralayer or higher level
LMEs. These attributes are accessed via the PLME-GET, PLME-SET, and PLME-RESET primitives
defined in Clause 6.

17.3.2 High Rate PHY MIB

All High Rate PHY MIB attributes are defined in Annex C, with specific values defined in Table 17-4.

17.3.4 High Rate TXTIME calculation

The value of the TXTIME parameter returned by the PLME-TXTIME.confirm primitive shall be calculated according to the following equation:

$$TXTIME = \text{PreambleLength} + \text{PLCPHeaderTime} + \text{Ceiling}(((\text{LENGTH}+\text{PBCC}) \times 8) / \text{DATARATE})$$

where

- \(\text{LENGTH}\) and \(\text{DATARATE}\) are values from the TXVECTOR parameter of the corresponding PLME-TXTIME.request primitive
- \(\text{LENGTH}\) is in units of octets
- \(\text{DATARATE}\) is in units of Mb/s
- \(\text{Ceiling}\) is a function that returns the smallest integer value greater than or equal to its argument value
- \(\text{PBCC}\) has a value of 1 if the SIGNAL value from the TXVECTOR parameter specifies PBCC and has a value of 0 otherwise
- The value of \(\text{PreambleLength}\) is 144 \(\mu\)s if the TXPREAMBLE_TYPE value from the TXVECTOR parameter indicates “LONGPREAMBLE,” or 72 \(\mu\)s if the TXPREAMBLE_TYPE value from the TXVECTOR parameter indicates “SHORTPREAMBLE”
- The value of \(\text{PLCPHeaderTime}\) is 48 \(\mu\)s if the TXPREAMBLE_TYPE value from the TXVECTOR parameter indicates “LONGPREAMBLE,” or 24 \(\mu\)s if the TXPREAMBLE_TYPE value from the TXVECTOR parameter indicates “SHORTPREAMBLE”

17.3.5 Vector descriptions

Several service primitives include a parameter vector. These vectors are a list of parameters as described in Table 17-6. DATARATE and LENGTH are described in 7.3.4.5. The remaining parameters are considered to be management parameters and are specific to this PHY.

17.4 High Rate PMD sublayer

17.4.1 Scope and field of application

The PMD services provided to the PLCP for the High Rate PHY are described in 17.4. Also defined in 17.4 are the functional, electrical, and RF characteristics required for interoperability of implementations conforming to this specification. The relationship of this specification to the entire High Rate PHY is shown in Figure 17-10.
17.4.2 Overview of service

The High Rate PMD sublayer accepts PLCP sublayer service primitives and provides the actual means by which data are transmitted or received from the medium. The combined functions of the High Rate PMD sublayer primitives and parameters for the receive function result in a data stream, timing information, and associated receive signal parameters being delivered to the PLCP sublayer. A similar functionality is provided for data transmission.

17.4.3 Overview of interactions

The primitives associated with the PLCP sublayer to the High Rate PMD fall into two basic categories:

a) Service primitives that support PLCP peer-to-peer interactions;

b) Service primitives that have local significance and that support sublayer-to-sublayer interactions.

17.4.4 Basic service and options

17.4.4.1 General

All of the service primitives described in 17.4.4 are considered mandatory, unless otherwise specified.

17.4.4.2 PMD_SAP peer-to-peer service primitives

Table 17-7 indicates the primitives for peer-to-peer interactions.

17.4.5 PMD_SAP detailed service specification

17.4.5.1 Introduction

The services provided by each PMD primitive are described in 17.4.5.2 to 17.4.5.16.

17.4.5.2 PMD_DATA.request

17.4.5.2.1 Function

This primitive defines the transfer of data from the PLCP sublayer to the PMD entity.

17.4.5.2.2 Semantics of the service primitive

This primitive provides the following parameter:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Associated primitive</th>
<th>Value (Mb/s)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TXD_UNIT</td>
<td>PMD_DATA.request</td>
<td>0,1: 1</td>
<td>This parameter represents a single block of data, which, in turn, is used by the PMD to be differentially encoded into a transmitted symbol. The symbol itself is spread by the PN code prior to transmission.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>00,01,11,10:2</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>X'0'–X'F': 5.5</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>X'00'–X'FF': 11</td>
<td></td>
</tr>
</tbody>
</table>
17.4.5.2.3 When generated

This primitive is generated by the PLCP sublayer to request transmission of a symbol. The data clock for this primitive is supplied by the PMD layer based on the PN code repetition.

17.4.5.2.4 Effect of receipt

The PMD performs the differential encoding, PN code modulation, and transmission of data.

17.4.5.3 PMD_DATA.indication

17.4.5.3.1 Function

This primitive defines the transfer of data from the PMD entity to the PLCP sublayer.

17.4.5.3.2 Semantics of the service primitive

This primitive provides the following parameter:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Associated primitive</th>
<th>Value (Mb/s)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RXD_UNIT</td>
<td>PMD_DATA.indication</td>
<td>0,1: 1</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>00,01,11,10:2</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>X'0' - X'F':</td>
<td>5.5</td>
</tr>
<tr>
<td></td>
<td></td>
<td>X'00' - X'FF':</td>
<td>11</td>
</tr>
</tbody>
</table>

This parameter represents a single symbol that has been demodulated by the PMD entity.

17.4.5.3.3 When generated

This primitive, which is generated by the PMD entity, forwards received data to the PLCP sublayer. The data clock for this primitive is supplied by the PMD layer based on the PN code repetition.

17.4.5.3.4 Effect of receipt

The PLCP sublayer either interprets the bit or bits that are recovered as part of the PLCP or passes the data to the MAC sublayer as part of the PSDU.

17.4.5.4 PMD_MODULATION.request

17.4.5.4.1 Function

This primitive, which is generated by the PHY PLCP sublayer, selects the modulation code that is used by the High Rate PHY for transmission.
17.4.5.4.2 Semantics of the service primitive

This primitive provides the following parameter:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Associated primitive</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MODULATION</td>
<td>PMD_MODULATION.request</td>
<td>1 MbBarker, 2 MbBarker, 5.5 CCK, 11 CCK, 5.5 PBCC, or 11 PBCC</td>
<td>In Receive mode, the MODULATION parameter informs the PLCP layer which PHY data modulation was used to process the PSDU portion of the PPDU. See 17.4.6.4 for further information on the High Rate PHY modulation codes.</td>
</tr>
<tr>
<td>MODULATION</td>
<td>PMD_MODULATION.indication</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

17.4.5.4.3 When generated

This primitive is generated by the PLCP sublayer to change or set the current High Rate PHY modulation code used for the PSDU portion of a PPDU. The PMD_MODULATION.request primitive is normally issued prior to issuing the PMD_TXSTART command.

17.4.5.4.4 Effect of receipt

The receipt of PMD_MODULATION selects the modulation that is used for all subsequent PSDU transmissions. This code is used for transmission only. The High Rate PHY shall still be capable of receiving all the required High Rate PHY modulations. This primitive, which is generated by the PMD entity, sets the state of the PHY for demodulation of the appropriate modulation.

17.4.5.5 PMD_PREAMBLE.request

17.4.5.5.1 Function

This primitive, which is generated by the PHY PLCP sublayer, selects the preamble mode that is used by the High Rate PHY for transmission.

17.4.5.5.2 Semantics of the service primitive

This primitive provides the following parameter:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Associated primitive</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PREAMBLE</td>
<td>PMD_PREAMBLE.request</td>
<td>0 for long</td>
<td>PREAMBLE selects which of the High Rate PHY preamble types is used for PLCP transmission. See 17.2.2 for further information on the High Rate PHY preamble modes.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1 for short</td>
<td></td>
</tr>
</tbody>
</table>

17.4.5.5.3 When generated

This primitive is generated by the PLCP sublayer to change or set the current High Rate PHY preamble mode used for the PLCP portion of a PPDU. The PMD_PREAMBLE.request primitive is normally issued prior to issuing the PMD_TXSTART command.
17.4.5.5.4 Effect of receipt

The receipt of PMD_PREAMBLE selects the preamble mode that is used for all subsequent PSDU transmissions. This mode is used for transmission only. The High Rate PHY shall still be capable of receiving all the required High Rate PHY preambles. This primitive sets the state of the PHY for modulation of the appropriate mode.

17.4.5.6 PMD_PREAMBLE.indication

17.4.5.6.1 Function

This primitive, which is generated by the PMD sublayer, indicates which preamble mode was used to receive the PLCP portion of the PPDU.

17.4.5.6.2 Semantics of the service primitive

This primitive provides the following parameter:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Associated primitive</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PREAMBLE</td>
<td>PMD_PREAMBLE.indication</td>
<td>0 for long, 1 for short</td>
<td>In RECEIVE mode, the PREAMBLE parameter informs the PLCP layer which of the High Rate PHY preamble modes was used to send the PLCP portion of the PPDU.</td>
</tr>
</tbody>
</table>

17.4.5.6.3 When generated

This primitive is generated by the PMD sublayer when the PLCP preamble has been properly detected.

17.4.5.6.4 Effect of receipt

This parameter is provided to the PLCP layer for information only.

17.4.5.7 PMD_TXSTART.request

17.4.5.7.1 Function

As a result of receiving a PHY_DATA.request primitive from the MAC, the PLCP issues this primitive, which initiates PPDU transmission by the PMD layer.

17.4.5.7.2 Semantics of the service primitive

This primitive has no parameters.

17.4.5.7.3 When generated

This primitive is generated by the PLCP sublayer to initiate the PMD layer transmission of the PPDU. The PHY-DATA.request primitive is provided to the PLCP sublayer prior to issuing the PMD_TXSTART command.

17.4.5.7.4 Effect of receipt

PMD_TXSTART initiates transmission of a PPDU by the PMD sublayer.
17.4.5.8 PMD_TXEND.request

17.4.5.8.1 Function

This primitive, which is generated by the PHY PLCP sublayer, ends PPDU transmission by the PMD layer.

17.4.5.8.2 Semantics of the service primitive

This primitive has no parameters.

17.4.5.8.3 When generated

This primitive is generated by the PLCP sublayer to terminate the PMD layer transmission of the PPDU.

17.4.5.8.4 Effect of receipt

PMD_TXEND terminates transmission of a PPDU by the PMD sublayer.

17.4.5.9 PMD_ANTSEL.request

17.4.5.9.1 Function

This primitive, which is generated by the PHY PLCP sublayer, selects the antenna used by the PHY for transmission or reception (when diversity is disabled).

17.4.5.9.2 Semantics of the service primitive

This primitive provides the following parameter:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Associated primitive</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ANT_STATE</td>
<td>PMD_ANTSEL.request</td>
<td>1 to 256</td>
<td>ANT_STATE selects which of the available antennas should be used for transmit. The number of available antennas is determined from the MIB table parameters, aSuprRxAntennas and aSuprTxAntennas.</td>
</tr>
<tr>
<td></td>
<td>PMD_ANTSEL.indication</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

17.4.5.9.3 When generated

This primitive is generated by the PLCP sublayer to select a specific antenna for transmission (or reception when diversity is disabled).

17.4.5.9.4 Effect of receipt

PMD_ANTSEL immediately selects the antenna specified by ANT_STATE.

17.4.5.10 PMD_TXPWRLVL.request

17.4.5.10.1 Function

This primitive, which is generated by the PHY PLCP sublayer, selects the power level used by the PHY for transmission.
17.4.5.10.2 Semantics of the service primitive

This primitive provides the following parameter:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Associated primitive</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TXPWR_LEVEL</td>
<td>PMD_TXPWRLEVEL.request</td>
<td>0, 1, 2, 3          (maximum of 4 levels)</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>TXPWR_LEVEL selects which of the optional transmit power levels should be used for the current PPDU transmission. The number of available power levels is determined by the MIB parameter dot11Number-SupportedPowerLevels. See 17.4.7.3 for further information on the optional High Rate PHY power-level control capabilities.</td>
</tr>
</tbody>
</table>

17.4.5.10.3 When generated

This primitive is generated by the PLCP sublayer to select a specific transmit power. This primitive is applied prior to setting PMD_TXSTART to the transmit state.

17.4.5.10.4 Effect of receipt

PMD_TXPWRLEVEL immediately sets the transmit power level given by TXPWR_LEVEL.

17.4.5.11 PMD_RATE.request

17.4.5.11.1 Function

This primitive, which is generated by the PHY PLCP sublayer, selects the data rate that shall be used by the High Rate PHY for transmission.

17.4.5.11.2 Semantics of the service primitive

This primitive provides the following parameter:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Associated primitive</th>
<th>Value (Mb/s)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RATE</td>
<td>PMD_RATE.indication</td>
<td>X'0A' or 1</td>
<td>RATE selects which of the High Rate PHY data rates is used for PS DU transmission. See 17.4.6.4 for further information on the High Rate PHY data rates. The High Rate PHY rate change capability is described in 17.2.</td>
</tr>
<tr>
<td></td>
<td>PMD_RATE.request</td>
<td>X'14' for 2</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>X'37' for 5.5</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>X'6E' for 11</td>
<td></td>
</tr>
</tbody>
</table>

17.4.5.11.3 When generated

This primitive is generated by the PLCP sublayer to change or set the current High Rate PHY data rate used for the PSDU portion of a PPDU.
17.4.5.11.4 Effect of receipt

The receipt of PMD_RATE selects the rate that is used for all subsequent PSDU transmissions. This rate is used for transmission only. The High Rate PHY shall still be capable of receiving all the required High Rate PHY data rates.

17.4.5.12 PMD_RSSI.indication

17.4.5.12.1 Function

This optional primitive may be generated by the PMD to provide the receive signal strength to the PLCP.

17.4.5.12.2 Semantics of the service primitive

This primitive provides the following parameter:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Associated primitive</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RSSI</td>
<td>PMD_RSSI.indication</td>
<td>0–8 bits of RSSI</td>
<td>The RSSI is a measure of the RF energy received by the High Rate PHY</td>
</tr>
</tbody>
</table>

17.4.5.12.3 When generated

This primitive is generated by the PMD when the High Rate PHY is in the receive state. It is continuously available to the PLCP, which, in turn, provides the parameter to the MAC entity.

17.4.5.12.4 Effect of receipt

This parameter is provided to the PLCP layer for information only. The RSSI may be used in conjunction with SQ as part of a CCA scheme.

17.4.5.13 PMD_SQ.indication

17.4.5.13.1 Function

This optional primitive may be generated by the PMD to provide an indication of the SQ of the High Rate PHY PN code correlation to the PLCP. SQ is a measure of the quality of BARKER code lock, providing an effective measure during the full reception of a PLCP preamble and header.

17.4.5.13.2 Semantics of the service primitive

This primitive provides the following parameter:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Associated primitive</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQ</td>
<td>PMD_SQ.indication</td>
<td>0–8 bits of SQ</td>
<td>This primitive is a measure of the SQ received by the HR/DSSS PHY</td>
</tr>
</tbody>
</table>
17.4.5.13.3 When generated

This primitive is generated by the PMD when the High Rate PHY is in the receive state and Barker code lock is achieved. It is continuously available to the PLCP, which, in turn, provides the parameter to the MAC entity.

17.4.5.13.4 Effect of receipt

This parameter is provided to the PLCP layer for information only. The SQ may be used in conjunction with RSSI as part of a CCA scheme.

17.4.5.14 PMD_CS.indication

17.4.5.14.1 General

This primitive, which is generated by the PMD, shall indicate to the PLCP layer that the receiver has acquired (locked) the Barker code and data are being demodulated.

17.4.5.14.2 Function

This primitive, which is generated by the PMD, shall indicate to the PLCP layer that the receiver has acquired (locked) the Barker code and data are being demodulated.

17.4.5.14.3 Semantics of the service primitive

This primitive provides the following parameter:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Associated primitive</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMD_CS</td>
<td>PMD_CS.indication</td>
<td>0 for DISABLED 1 for ENABLED</td>
<td>The PMD_CS primitive, in conjunction with PMD_ED, provides CCA status through the PLCP layer PHYCCA primitive. PMD_CS indicates a binary status of ENABLED or DISABLED. PMD_CS is ENABLED when the correlator SQ indicated in PMD_SQ is greater than the correlation threshold. PMD_CS is DISABLED when the PMD_SQ falls below the correlation threshold.</td>
</tr>
</tbody>
</table>

17.4.5.14.4 When generated

This primitive is generated by the PMD sublayer when the High Rate PHY is receiving a PPDU and the PN code has been acquired.

17.4.5.14.5 Effect of receipt

This indicator is provided to the PLCP for forwarding to the MAC entity for information purposes through the PHY-CCA indicator. This parameter shall indicate that the RF medium is busy and occupied by a High Rate PHY signal. The High Rate PHY should not be placed into the transmit state when PMD_CS is ENABLED.
17.4.5.15 PMD_ED.indication

17.4.5.15.1 Function

This optional primitive may be generated by the PMD to provide an indication that the receiver has detected RF energy indicated by the PMD_RSSI primitive that is above a predefined threshold.

17.4.5.15.2 Semantics of the service primitive

This primitive provides the following parameter:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Associated primitive</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMD_ED</td>
<td>PMD_ED.indication</td>
<td>0 for DISABLED 1 for ENABLED</td>
<td>The PMD_ED primitive, along with the PMD_SQ, provides CCA status at the PLCP layer through the PHY-CCA primitive. PMD_ED indicates a binary status of ENABLED or DISABLED. PMD_ED is ENABLED when the RSSI in PMD_RSSI is greater than the ED_THRESHOLD parameter. PMD_ED is DISABLED when the PMD_RSSI falls below the energy detect threshold.</td>
</tr>
</tbody>
</table>

17.4.5.15.3 When generated

This primitive is generated by the PHY when the PHY is receiving RF energy from any source that exceeds the ED_THRESHOLD parameter.

17.4.5.15.4 Effect of receipt

This indicator is provided to the PLCP for forwarding to the MAC entity for information purposes through the PMD_ED indicator. This parameter shall indicate that the RF medium may be busy with an RF energy source that is not High Rate PHY compliant. If a High Rate PHY source is being received, the PMD_CS function is enabled shortly after the PMD_ED function is enabled.

17.4.5.16 PMD_ED.request

17.4.5.16.1 Function

This optional primitive may be generated by the PLCP to set a value for the energy detect ED_THRESHOLD.

17.4.5.16.2 Semantics of the service primitive

This primitive provides the following parameter:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Associated primitive</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMD_ED</td>
<td>PMD_ED.request</td>
<td>ED_THRESHOLD</td>
<td>ED_THRESHOLD is the threshold that the RSSI should be greater than in order for PMD_ED to be enabled. PMD_ED is DISABLED when the PMD_RSSI falls below the energy detect threshold.</td>
</tr>
</tbody>
</table>
17.4.5.16.3 When generated

This primitive is generated by the PLCP sublayer to change or set the current High Rate PHY energy detect threshold.

17.4.5.16.4 Effect of receipt

The receipt of PMD_ED immediately changes the energy detect threshold as set by the ED_THRESHOLD parameter.

17.4.5.17 PMD_RCPI.indication

17.4.5.17.1 Function

This optional primitive, generated by the PMD sublayer, provides the RCPI to the PLCP and MAC.

17.4.5.17.2 Semantics of the service primitive

The primitive shall provide the following parameter:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Associated primitive</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RCPI</td>
<td>PMD_RCPI.indication</td>
<td>0–255</td>
<td>The RCPI is a measure of the received power by the High Rate PHY as defined in 17.4.8.6.</td>
</tr>
</tbody>
</table>

17.4.5.17.3 When generated

This primitive shall be generated by the PMD when the High Rate PHY is in the receive state when dot11RadioMeasurementActivated is true. It is continuously available to the PLCP, which in turn provides the parameter to the MAC entity.

17.4.5.17.4 Effect of receipt

This parameter shall be provided to the PLCP layer for information only. The RCPI may be used in conjunction with RSNI to measure input signal quality.

17.4.6 PMD operating specifications, general

17.4.6.1 General

General specifications for the High Rate PMD sublayer are provided in 17.4.6.2 to 17.4.6.14. These specifications apply to both the receive and transmit functions and general operation of a High Rate PHY.

WLANs implemented in accordance with this standard are subject to equipment certification and operation requirements established by regional and national regulatory administrations. The PMD specification establishes minimum technical requirements for interoperability, based upon established regulations at the time this standard was issued. These regulations are subject to revision, or may be superseded. Requirements that are subject to local geographic regulations are annotated within the PMD specification. Regulatory requirements that do not affect interoperability are not addressed in this standard. Implementers are referred to the following regulatory sources for further information. Operation in countries within defined regulatory domains may be subject to additional regulations.
17.4.6.2 Operating frequency range

The High Rate PHY shall operate in the 2.4–2.4835 GHz frequency range, as allocated by regulatory bodies in the China, United States, Europe, and Japan, or in the 2.471–2.497 GHz frequency range, as allocated by regulatory authority in Japan.

17.4.6.3 Channel Numbering of operating channels

When dot11OperatingClassesRequired is true, channel numbering shall be as specified in 18.3.8.4.2 and channelization shall be as specified in 18.3.8.4.3. When dot11OperatingClassesDefined is false or not defined, the channel center frequencies and CHNL_ID numbers shall be as shown in Table 17-9. See the applicable regulations for the countries in which the implementation operates.

</table>

In a multiple cell network topology, overlapping and/or adjacent cells using different channels can operate simultaneously without interference if the distance between the center frequencies is at least 25 MHz. Channel 14 shall be designated specifically for operation in Japan.

17.4.6.4 Modulation and channel data rates

Four modulation formats and data rates are specified for the High Rate PHY. The basic access rate shall be based on 1 Mb/s DBPSK modulation. The enhanced access rate shall be based on 2 Mb/s DQPSK. The extended direct sequence specification defines two additional data rates. The High Rate access rates shall be based on the CCK modulation scheme for 5.5 Mb/s and 11 Mb/s. An optional PBCC mode is also provided for potentially enhanced performance.
17.4.6.5 Spreading sequence and modulation for 1 Mb/s and 2 Mb/s

The following 11-chip Barker sequence shall be used as the PN code sequence for the 1 Mb/s and 2 Mb/s modulation:

\[+1, -1, +1, +1, -1, +1, +1, -1, -1, -1\]

The leftmost chip shall be output first in time. The first chip shall be aligned at the start of a transmitted symbol. The symbol duration shall be exactly 11 chips long.

The DBPSK encoder for the basic access rate is specified in Table 17-10. The DQPSK encoder is specified in Table 17-11. (In these tables, \(+j\omega\) shall be defined as counterclockwise rotation.)

| Table 17-10—1 Mb/s DBPSK encoding table |

| 10 | \(3\pi/2 \((-\pi/2)\)\) |

17.4.6.6 Spreading sequences and modulation for CCK modulation at 5.5 Mb/s and 11 Mb/s

17.4.6.6.1 General

For the CCK modulation modes, the spreading code length is 8 and is based on complementary codes. The chipping rate is 11 Mchip/s. The symbol duration shall be exactly 8 complex chips long.

The following formula shall be used to derive the CCK codewords that shall be used for spreading both 5.5 Mb/s and 11 Mb/s

\[
C = \{e^{j(\varphi_1 + \varphi_2 + \varphi_3 + \varphi_4)}, e^{j(\varphi_1 + \varphi_3 + \varphi_4)}, e^{j(\varphi_1 + \varphi_2 + \varphi_3)}, e^{j(\varphi_1 + \varphi_3 + \varphi_4)}, e^{j(\varphi_1 + \varphi_2)}, e^{j(\varphi_1 + \varphi_3)}, e^{j(\varphi_1 + \varphi_2 + \varphi_3)}, e^{j(\varphi_1 + \varphi_3 + \varphi_4)}\} \tag{17-1}
\]

where \(C\) is the codeword

\[C = \{c_0 \text{ to } c_7\}\]

The terms \(\varphi_1, \varphi_2, \varphi_3,\) and \(\varphi_4\) are defined in 17.4.6.6.3 for 5.5 Mb/s and 17.4.6.6.4 for 11 Mb/s.

This formula creates 8 complex chips \((c_0 \text{ to } c_7)\), where \(c_0\) is transmitted first in time.
This is a form of the generalized Hadamard transform encoding, where $\phi_1$ is added to all code chips, $\phi_2$ is added to all odd code chips, $\phi_3$ is added to all odd pairs of code chips, and $\phi_4$ is added to all odd groups of four code chips.

The term $\phi_1$ modifies the phase of all code chips of the sequence and shall be DQPSK encoded for 5.5 Mb/s and 11 Mb/s. This shall take the form of rotating the whole symbol by the appropriate amount relative to the phase of the preceding symbol. Note that the chip c7 of the symbol defined above is the chip that indicates the symbol’s phase and is transmitted last.

17.4.6.6.2 Cover code for CCK

The fourth and seventh chips are rotated 180° by a cover sequence to optimize the sequence correlation properties and minimize dc offsets in the codes. This explains the minus sign on the fourth and seventh terms in Equation (17-1).

17.4.6.6.3 CCK 5.5 Mb/s modulation

At 5.5 Mb/s, 4 bits (d0 to d3; d0 first in time) are transmitted per symbol.

The data bits d0 and d1 encode $\phi_1$ based on DQPSK. The DQPSK encoder is specified in Table 17-11. (In the table, $+j\omega$ shall be defined as counterclockwise rotation.) The phase change for $\phi_1$ is relative to the phase $\phi_1$ of the preceding symbol. For the header to PSDU transition, the phase change for $\phi_1$ is relative to the phase of the preceding DQPSK (2 Mb/s) symbol. That is, the phase of the last symbol of the CRC-16 is the reference phase for the first symbol generated from the PSDU octets. (See the definition in 17.4.6.5 for the reference phase of this Barker coded symbol.) A “+1” chip in the Barker code shall represent the same carrier phase as a “+1” chip in the CCK code.

All odd-numbered symbols generated from the PSDU octets shall be given an extra 180 degree ($\pi$) rotation, in addition to the standard DQPSK modulation as shown in Table 17-12. The symbols of the PSDU shall be numbered starting with 0 for the first symbol, for the purposes of determining odd and even symbols. That is, the PSDU transmission starts on an even-numbered symbol.

The data dibits d2 and d3 CCK encode the basic symbol, as specified in Table 17-13. This table is derived from the formula above by setting $\phi_2 = (d2 \times \pi) / 2$, $\phi_3 = 0$, and $\phi_4 = d3 \times \pi$. In this table, d2 and d3 are in the order shown, and the complex chips are shown c0 to c7 (left to right), with c0 transmitted first in time.
17.4.6.6.4 CCK 11 Mb/s modulation

At 11 Mb/s, 8 bits (d0 to d7; d0 first in time) are transmitted per symbol.

The first dibit (d0, d1) encodes \( \phi_1 \) based on DQPSK. The DQPSK encoder is specified in Table 17-11. The phase change for \( \phi_1 \) is relative to the phase \( \phi_1 \) of the preceding symbol. In the case of header to PSDU transition, the phase change for \( \phi_1 \) is relative to the phase of the preceding DQPSK symbol. All odd-numbered symbols of the PSDU are given an extra 180 degree (\( \pi \)) rotation, in accordance with the DQPSK modulation shown in Table 17-11. Symbol numbering starts with 0 for the first symbol of the PSDU.

The data dibits (d2, d3), (d4, d5), and (d6, d7) encode \( \phi_2, \phi_3, \) and \( \phi_4 \), respectively, based on QPSK as specified in Table 17-14. Note that this table is binary (not Gray) coded.

17.4.6.7 DSSS/PBCC data modulation and modulation rate (optional)

This optional coding scheme uses a binary convolutional coding with a 64-state binary convolutional code (BCC) and a cover sequence. The output of the BCC is encoded jointly onto the I and Q channels, as described in this subclause.

The encoder for this scheme is shown in Figure 17-11. Incoming data are first encoded with a binary convolutional code. A cover code is applied to the encoded data prior to transmission through the channel.
The BCC that is used is a 64-state, rate ½ code. The generator matrix for the code is given as

\[ G = \begin{bmatrix} D^6 + D^4 + D^3 + D + 1, & D^6 + D^5 + D^4 + D^2 + 1 \end{bmatrix} \]

or in octal notation, it is given by

\[ G = [133, 175] \]

Because the system is frame (PPDU) based, the encoder shall be in state zero (i.e., all memory elements contain 0 at the beginning of each PPDU). The encoder is also be placed in a known state at the end of each PPDU to prevent the data bits near the end of the PPDU from being substantially less reliable than those early on in the PPDU. To place the encoder in a known state at the end of a PPDU, at least six deterministic bits shall be input immediately following the last data bit input to the convolutional encoder. This is achieved by appending 1 octet containing all zeros to the end of the PPDU prior to transmission, and discarding the final octet of each received PPDU. In this manner, the decoding process can be completed reliably on the last data bits.

An encoder block diagram is shown in Figure 17-12. It consists of six memory elements. For every data bit input, two output bits are generated.

The output of the binary convolutional code described above is mapped to a constellation using one of two possible rates. The 5.5 Mb/s rate uses BPSK, and the 11 Mb/s rate uses QPSK. In QPSK mode, each pair of output bits from the binary convolutional code is used to produce one symbol; in BPSK mode, each pair of bits from the BCC is taken serially (\(y_0\) first) and used to produce two BPSK symbols. This yields a throughput of one bit per symbol in QPSK mode and one-half a bit per symbol in BPSK mode.
The phase of the first complex chip of the PSDU shall be defined with respect to the phase of the last chip of the PCLP header (i.e., the last chip of the CRC check). The bits \((y_1 y_0) = (0, 0)\) shall indicate the same phase as the last chip of the CRC check. The other three combinations of \((y_1 y_0)\) shall be defined with respect to this reference phase, as shown in Figure 17-13.

The mapping from BCC outputs to PSK constellation points in BPSK and QPSK modes is determined by a pseudorandom cover sequence. This is shown for both modes in Figure 17-13. Note that this is an absolute phase table, not differential as in CCK.

The pseudorandom cover sequence is generated from a seed sequence. The 16-bit seed sequence is 0011001110001011, where the first bit of the sequence in time is the leftmost bit. This sequence in octal notation is given as 150714, where the LSB is the first in time. This seed sequence is used to generate the 256-bit pseudorandom cover sequence, which is used in the mapping of the current PSK symbol. It is the current binary value of this sequence at every given point in time that is taken as \(S\) in Figure 17-13.

This sequence of 256 bits is produced by taking the first sixteen bits of the sequence as the seed sequence, the second sixteen bits as the seed sequence cyclically left rotated by three, the third sixteen bits as the seed sequence cyclically left rotated by six, etc. If \(c_i\) is the \(i^{th}\) bit of the seed sequence, where \(0 \leq i \leq 15\), then the sequence that is used to cover the data is given row-wise as follows:

\[
\begin{array}{cccccccccccccccc}
0 & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 & 12 & 13 & 14 & 15 \\
0 & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 & 12 & 13 & 14 & 15 \\
0 & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 & 12 & 13 & 14 & 15 \\
0 & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 & 12 & 13 & 14 & 15 \\
0 & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 & 12 & 13 & 14 & 15 \\
0 & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 & 12 & 13 & 14 & 15 \\
\end{array}
\]

Figure 17-13—Cover code mapping
For PPDUs with more than 256 data bits, this sequence of 256 bits is simply repeated.

17.4.6.8 Channel Agility (optional)

17.4.6.8.1 General

This Channel Agility option allows an implementation to overcome some inherent difficulty with static channel assignments (a tone jammer), without burdening all implementations with the added cost of this capability. When the Channel Agility option is enabled, the PHY shall meet the requirements on channel switching and settling time, as described in 17.4.6.13, and the hop sequences described below. This option can also be used to implement IEEE 802.11-compliant systems that are interoperable between both FH and DS modulations. Annex K contains a description of the expected behavior when such networks are employed.

17.4.6.8.2 Hop sequences

The hop sequences for each of the specified geographical areas are defined with two sets. High Rate frequency channels referred to in this subclause are defined in Table 17-9.

The first set (Figure 17-14 and Figure 17-16) uses nonoverlapping frequency channels to allow the High Rate systems to minimize interference degradation. The synchronization of FH is performed by the MLME, as defined in 10.1.6 for the FH PHY. The PLME SAP service primitives used to command a new frequency channel are defined in 6.5.

The second set (Figure 17-15 and Figure 17-17) uses half overlapping frequency channels, with 10 MHz center frequency spacing, to enable interoperability with 1 Mb/s and 2 Mb/s FH systems hopping with the approved IEEE 802.11 hop sequences. The High Rate hop frequency is calculated from the specific 1 MHz channel chosen for a given hop by picking the closest High Rate channel within the set. Where there is a choice of two DSSS channels, the lower one shall be the one chosen. Therefore, the chosen channel shall be no more than ±5 MHz of the channel center of the FH channel. When operating on the FH channels beyond ±5 MHz of the closest High Rate channel specified in the set, the High Rate mode shall not be used and all FH transmissions shall occur at the 1 Mb/s or 2 Mb/s rate.
17.4.6.8.3 Operating channels

The operating channels for specified geographical areas are defined in Table 17-15 and Table 17-16.

Table 17-15—China and North American operating channels

</tbody>
</table>
17.4.6.8.4 Hop patterns

An FH pattern, Fx, consists of a permutation of all frequency channels defined in Table 17-15 and Table 17-16. For a given pattern number x, the hopping sequence is as follows:

\[ F_x = \{ f_x(1), f_x(2), ..., f_x(p) \} \]

where
\[ f_x(i) \]

is the channel number (as defined in 14.7.4) for \( i^{th} \) frequency in the \( x^{th} \) hopping pattern

\[ p \]

is the number of hops in pseudorandom hopping pattern before repeating sequence (79 for North America and most of Europe)

The FH patterns for Set 1 of each geographic area are based on the hop patterns in Table 17-17 and Table 17-18.

**Table 17-17—China and North American Set 1 hop patterns**

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

The FH patterns for Set 2 of each geographic area are defined by the 1/2 Mb/s FH PHY hop sequences, as described in the FH PHY (14.7.8). Given the hopping pattern number x, and the index for the next frequency, i (in the range 1 to p), the DS channel number (as defined in 17.4.6.3) shall be selected with the following algorithm:

**China and North America**

\[ f'_x(i) = f_x(i) \text{ for } 1 \leq f_x(i) \leq 11; \]
\[ f'_x(i) = \text{null for } f_x(i) < 1 \text{ and } f_x(i) > 11; \]
\[ f'_x(i) = 2 \times \text{Int} \left[ \left( \left\lfloor b(i) + x \right\rfloor \mod (79) + 2 \right) / 10 \right] - 1; \]
with \( b(i) \) defined in Table 14-11 (in 14.7.8).

**Most of Europe**

\[ f'_x(i) = f_x(i) \text{ for } 1 \leq f_x(i) \leq 13; \]
\[ f'_x(i) = \text{null for } f_x(i) < 1 \text{ and } f_x(i) > 13; \]
\[ f'_x(i) = 2 \times \text{Int} \left[ \left( \left\lfloor b(i) + x \right\rfloor \mod (79) + 2 \right) / 10 \right] - 1; \]
with \( b(i) \) defined in Table 14-11 (in 14.7.8).
17.4.6.9 Transmit and receive in-band and out-of-band spurious emissions

The High Rate PHY conforms with in-band and out-of-band spurious emissions as set by the appropriate regulatory bodies.

17.4.6.10 TX-to-RX turnaround time

The TX-to-RX turnaround time shall be less than 10 μs, including the power-down ramp specified in 17.4.7.7.

The TX-to-RX turnaround time shall be measured at the air interface from the trailing edge of the last transmitted symbol to the valid CCA detection of the incoming signal. The CCA should occur within 25 μs (10 μs for turnaround time, plus 15 μs for energy detect), or by the next slot boundary occurring after the 25 μs has elapsed (see 17.4.8.5). A receiver input signal 3 dB above the ED threshold described in 17.4.8.5 shall be present at the receiver.

17.4.6.11 RX-to-TX turnaround time

The RX-to-TX turnaround time shall be measured at the MAC/PHY interface using the PHY-TXSTART.request primitive, and shall be 5 μs. This includes the transmit power-on ramp described in 17.4.7.7.

17.4.6.12 Slot time

The slot time for the High Rate PHY shall be the sum of the RX-to-TX turnaround time (5 μs) and the energy detect time (15 μs specified in 17.4.8.5). The propagation delay shall be regarded as being included in the energy detect time.

17.4.6.13 Channel switching/settling time

When the Channel Agility option is enabled, the time to change from one operating channel frequency to another, as specified in 17.4.6.3, is 224 μs. A conformant PMD meets this switching time specification when the operating channel center frequency has settled to within ±60 kHz of the nominal channel center. STAs shall not transmit until after the channel change settling time.

17.4.6.14 Transmit and receive antenna port impedance

The impedance of the transmit and receive antenna port(s) shall be 50 Ω if the port is exposed.

17.4.7 PMD transmit specifications

17.4.7.1 Introduction

The transmit functions and parameters associated with the PMD sublayer are described in 17.4.7.2 to 17.4.7.9.

17.4.7.2 Transmit power levels

The maximum allowable output power is measured in accordance with practices specified by the appropriate regulatory bodies.
17.4.7.3 Transmit power level control

Power control shall be provided for transmitted power greater than 100 mW. A maximum of four power levels may be provided. As a minimum, a radio capable of transmission greater than 100 mW shall be capable of switching power back to 100 mW or less.

17.4.7.4 Transmit spectrum mask

The transmitted spectral products shall be less than −30 dB (decibel relative to the SINx/x peak) for
\[ f_c - 22 \text{ MHz} < f < f_c - 11 \text{ MHz}; \text{ and} \]
\[ f_c + 11 \text{ MHz} < f < f_c + 22 \text{ MHz}; \]
and shall be less than −50 dB for
\[ f < f_c - 22 \text{ MHz}; \text{ and} \]
\[ f > f_c + 22 \text{ MHz}. \]

where
\[ f_c \] is the channel center frequency

The transmit spectral mask is shown in Figure 17-18. The measurements shall be made using a 100 kHz resolution bandwidth and a 100 kHz video bandwidth.

17.4.7.5 Transmit center frequency tolerance

The transmitted center frequency tolerance shall be ±25 ppm maximum.

17.4.7.6 Chip clock frequency tolerance

The PN code chip clock frequency tolerance shall be better than ±25 ppm maximum. It is highly recommended that the chip clock and the transmit frequency be locked (coupled) for optimum demodulation performance. If these clocks are locked, it is recommended that bit 2 of the SERVICE field be set to 1, as indicated in 17.2.3.5.
17.4.7.7 Transmit power-on and power-down ramp

The transmit power-on ramp for 10% to 90% of maximum power shall be no greater than 2 $\mu$s. The transmit power-on ramp is shown in Figure 17-19.

![Transmit power-on ramp diagram](image)

**Figure 17-19—Transmit power-on ramp**

The transmit power-down ramp for 90% to 10% maximum power shall be no greater than 2 $\mu$s. The transmit power-down ramp is shown in Figure 17-20.

![Transmit power-down ramp diagram](image)

**Figure 17-20—Transmit power-down ramp**

The transmit power ramps shall be constructed such that the High Rate PHY emissions conform with spurious frequency product specification defined in 17.4.6.9.

17.4.7.8 RF carrier suppression

The RF carrier suppression, measured at the channel center frequency, shall be at least 15 dB below the peak SIN(x)/x power spectrum. The RF carrier suppression shall be measured while transmitting a repetitive 01 data sequence with the scrambler disabled using DQPSK modulation. A 100 kHz resolution bandwidth shall be used to perform this measurement.
17.4.7.9 Transmit modulation accuracy

The transmit modulation accuracy requirement for the High Rate PHY shall be based on the difference between the actual transmitted waveform and the ideal signal waveform. Modulation accuracy shall be determined by measuring the peak vector error magnitude during each chip period. Worst-case vector error magnitude shall not exceed 0.35 for the normalized sampled chip data. The ideal complex I and Q constellation points associated with DQPSK modulation, (0.707, 0.707), (0.707, −0.707), (−0.707, 0.707), (−0.707, −0.707), shall be used as the reference. These measurements shall be from baseband I and Q sampled data after recovery through a reference receiver system.

Figure 17-21 illustrates the ideal DQPSK constellation points and range of worst-case error specified for modulation accuracy.

Error vector measurement requires a reference receiver capable of carrier lock. All measurements shall be made under carrier lock conditions. The distortion induced in the constellation by the reference receiver shall be calibrated and measured. The test data error vectors described below shall be corrected to compensate for the reference receiver distortion.

The IEEE 802.11-compatible radio shall provide an exposed TX chip clock, which shall be used to sample the I and Q outputs of the reference receiver.

The measurement shall be made under the conditions of continuous DQPSK transmission using scrambled all ones.

The eye pattern of the I channel shall be used to determine the I and Q sampling point. The chip clock provided by the vendor radio shall be time delayed, such that the samples fall at a 1/2 chip period offset from the mean of the zero crossing positions of the eye (see Figure 17-22). This is the ideal center of the eye and may not be the point of maximum eye opening.
Using the aligned chip clock, 1000 samples of the I and Q baseband outputs from the reference receiver are captured. The vector error magnitudes shall be calculated as follows:

Calculate the dc offsets for I and Q samples

\[
I_{\text{mean}} = \frac{1}{1000} \sum_{n=0}^{999} I(n)
\]

\[
Q_{\text{mean}} = \frac{1}{1000} \sum_{n=0}^{999} Q(n)
\]

Calculate the dc corrected I and Q samples for all \(n = 1000\) sample pairs

\[
I_{dc}(n) = I(n) - I_{\text{mean}}
\]

\[
Q_{dc}(n) = Q(n) - Q_{\text{mean}}
\]

Calculate the average magnitude of I and Q samples

\[
I_{\text{mag}} = \frac{1}{1000} \sum_{n=0}^{999} |I_{dc}(n)|
\]

\[
Q_{\text{mag}} = \frac{1}{1000} \sum_{n=0}^{999} |Q_{dc}(n)|
\]

Calculate the normalized error vector magnitude for the \(I_{dc}(n)/Q_{dc}(n)\) pairs
\[ V_{err}(n) = \left[ \left( \frac{|I_{dc}(n)|}{I_{mag}} - 1 \right)^2 + \left( \frac{|Q_{dc}(n)|}{Q_{mag}} - 1 \right)^2 \right]^{1/3} - V_{\text{correction}} \]

where

\[ V_{\text{correction}} \] is the error induced by the reference receiver system

A vendor High Rate PHY implementation shall be compliant if for all \( n = 1000 \) samples, the following condition is met:

\[ V_{err}(n) < 0.35 \]

### 17.4.7.10 Time of Departure accuracy

The Time of Departure accuracy test evaluates \( \text{TIME\_OF\_DEPARTURE} \) against \( \text{aTxPmdTxStartRMS} \) and \( \text{aTxPmdTxStartRMS} \) against \( \text{TIME\_OF\_DEPARTURE\_ACCURACY\_TEST\_THRESH} \) as defined in Annex T with the following test parameters:

- \( \text{MULTICHANNEL\_SAMPLING\_RATE} = 22 \times 10^6 \left( 1 + \left\lceil \frac{f_H - f_L}{22 \text{ MHz}} \right\rceil \right) \) sample/s
  - where
    - \( f_H \) is the nominal center frequency in Hz of the highest channel in the channel set
    - \( f_L \) is the nominal center frequency in Hz of the lowest channel in the channel set, the channel set is the set of channels upon which frames providing measurements are transmitted, the channel set comprises channels uniformly spaced across \( f_H - f_L \geq 50 \text{ MHz} \)
    - \( \lceil x \rceil \) equals the smallest integer equal to or larger than \( x \)
- \( \text{FIRST\_TRANSITION\_FIELD} \) is the SYNC field.
- \( \text{SECOND\_TRANSITION\_FIELD} \) is the SFD field.
- \( \text{TRAINING\_FIELD} \) is the concatenation of the appropriate short or long SYNC and SFD fields, using a chip pulse which should approximate a rectangular pulse of duration \( 1/11 \text{ MHz} \) convolved with a brick-wall low pass filter of bandwidth 11 MHz.
- \( \text{TIME\_OF\_DEPARTURE\_ACCURACY\_TEST\_THRESH} \) is 80 ns.

NOTE—The indicated chip pulse applies to the time of departure accuracy test equipment, and not the transmitter or receiver.

### 17.4.8 PMD receiver specifications

#### 17.4.8.1 Introduction

The receive functions and parameters associated with the PMD sublayer are described in 17.4.8.2 to 17.4.8.5.

#### 17.4.8.2 Receiver minimum input level sensitivity

The FER shall be less than \( 8 \times 10^{-2} \) at a PSDU length of 1024 octets for an input level of \( -76 \text{ dBm} \) measured at the antenna connector. This FER shall be specified for 11 Mb/s CCK modulation. The test for the minimum input level sensitivity shall be conducted with the ED threshold set less than or equal to \( -76 \text{ dBm} \).

#### 17.4.8.3 Receiver maximum input level

The receiver shall provide a maximum FER of \( 8 \times 10^{-2} \) at a PSDU length of 1024 octets for a maximum input level of \( -10 \text{ dBm} \) measured at the antenna. This FER shall be specified for 11 Mb/s CCK modulation.
17.4.8.4 Receiver adjacent channel rejection

Adjacent channel rejection is defined between any two channels with ≥ 25 MHz separation in each channel group, as defined in 17.4.6.3.

The adjacent channel rejection shall be equal to or better than 35 dB, with an FER of $8 \times 10^{-2}$ using 11 Mbit/s CCK modulation described in 17.4.6.4 and a PSDU length of 1024 octets.

The adjacent channel rejection shall be measured using the following method.

Input an 11 Mb/s CCK modulated signal at a level 6 dB greater than specified in 17.4.8.2. In an adjacent channel (≥ 25 MHz separation as defined by the channel numbering), input a signal modulated in a similar fashion, which adheres to the transmit mask specified in 17.4.7.4, to a level 41 dB above the level specified in 17.4.8.2. The adjacent channel signal shall be derived from a separate signal source. It shall not be a frequency shifted version of the reference channel. Under these conditions, the FER shall be no worse than $8 \times 10^{-2}$.

17.4.8.5 CCA

The High Rate PHY shall provide the capability to perform CCA according to at least one of the following three methods:

- CCA Mode 1: Energy above threshold. CCA shall report a busy medium upon detecting any energy above the ED threshold.
- CCA Mode 4: CS with timer. CCA shall start a timer whose duration is 3.65 ms and report a busy medium only upon the detection of a High Rate PHY signal. CCA shall report an IDLE medium after the timer expires and no High Rate PHY signal is detected. The 3.65 ms timeout is the duration of the longest possible 5.5 Mb/s PSDU.
- CCA Mode 5: A combination of CS and energy above threshold. CCA shall report busy at least while a High Rate PPDU with energy above the ED threshold is being received at the antenna.

The ED status shall be given by the PMD primitive, PMD_ED. The CS status shall be given by PMD_CS. The status of PMD_ED and PMD_CS is used in the PLCP to indicate activity to the MAC through the PHY-CCA.indication primitive.

A busy channel shall be indicated by PHY-CCA.indication primitive of class BUSY. A clear channel shall be indicated by PHY-CCA.indication primitive of class IDLE.

dot11CCAModeSupported shall indicate the appropriate operation modes. The PHY shall be configured through dot11CurrentCCAMode.

The CCA shall indicate true if there is no energy detect or CS. The CCA parameters are subject to the following criteria:

a) If a valid High Rate signal is detected during its preamble within the CCA window, the ED threshold shall be less than or equal to $-76 \text{ dBm}$ for TX power $> 100 \text{ mW}$; $-73 \text{ dBm}$ for $50 \text{ mW} < \text{TX power} \leq 100 \text{ mW}$; and $-70 \text{ dBm}$ for $\text{TX power} \leq 50 \text{ mW}$.

b) With a valid signal (according to the CCA mode of operation) present at the receiver antenna within 5 μs of the start of a MAC slot boundary, the CCA indicator shall report channel busy before the end of the slot time. This implies that the CCA signal is available as an exposed test point. Refer to Figure 9-14 (in 9.3.7) for a slot time boundary definition.

c) In the event that a correct PLCP header is received, the High Rate PHY shall hold the CCA signal inactive (channel busy) for the full duration, as indicated by the PLCP LENGTH field. Should a loss of CS occur in the middle of reception, the CCA shall indicate a busy medium for the intended...
duration of the transmitted PPDU. Upon reception of a correct PLCP header, the timer of CCA Mode 2 shall be overridden by this requirement.

Conformance to the High Rate PHY CCA shall be demonstrated by applying an equivalent High-Rate-compliant signal above the appropriate ED threshold (item a) so that all conditions described in item b and item c are demonstrated.

### 17.4.8.6 Received Channel Power Indicator Measurement

The RCPI indicator is a measure of the received RF power in the selected channel for a received frame. This parameter shall be a measure by the PHY sublayer of the received RF power in the channel measured over the entire received frame or by other equivalent means that meet the specified accuracy. RCPI shall be a monotonically increasing, logarithmic function of the received power level defined in dBm. The allowed values for the RCPI parameter shall be an 8-bit value in the range from 0 to 220, with indicated values rounded to the nearest 0.5 dB as follows:

0: Power ≤ –110 dBm
1: Power = –109.5 dBm
2: Power = –109.0 dBm

and so on where

\[
RCPI = \text{Int}\{(\text{Power in dBm} + 110) \times 2\} \text{ for 0 dBm} \geq \text{Power} \geq –110 \text{ dBm}
\]

220: Power ≥ 0 dBm

221–254: Reserved

255: Measurement not available

RCPI shall equal the received RF power within an accuracy of ±5 dB (95% confidence interval) within the specified dynamic range of the receiver. The received RF power shall be determined assuming a receiver noise equivalent bandwidth equal to the channel bandwidth multiplied by 1.1.
18. Orthogonal frequency division multiplexing (OFDM) PHY specification

18.1 Introduction

18.1.1 General

This clause specifies the PHY entity for an orthogonal frequency division multiplexing (OFDM) system. The OFDM system provides a WLAN with data payload communication capabilities of 6, 9, 12, 18, 24, 36, 48, and 54 Mb/s. The support of transmitting and receiving at data rates of 6, 12, and 24 Mb/s is mandatory. The system uses 52 subcarriers that are modulated using binary or quadrature phase shift keying (BPSK or QPSK) or using 16- or 64-quadrature amplitude modulation (16-QAM or 64-QAM). Forward error correction coding (convolutional coding) is used with a coding rate of 1/2, 2/3, or 3/4.

The OFDM system also provides a “half-clocked” operation using 10 MHz channel spacings with data communications capabilities of 3, 4.5, 6, 9, 12, 18, 24, and 27 Mb/s. The support of transmitting and receiving at data rates of 3, 6, and 12 Mb/s is mandatory when using 10 MHz channel spacing. The half-clocked operation doubles symbol times and clear channel assessment (CCA) times when using 10 MHz channel spacing. The regulatory requirements and information regarding use of this OFDM PHY are in Annex D and Annex E.

The OFDM system also provides a “quarter-clocked” operation using 5 MHz channel spacing with data communication capabilities of 1.5, 2.25, 3, 4.5, 6, 9, 12, and 13.5 Mb/s. The support of transmitting and receiving at data rates of 1.5, 3, and 6 Mb/s is mandatory when using 5 MHz channel spacing. The quarter-clocked operation quadruples symbol times and CCA times when using 5 MHz channel spacing. The regulatory requirements and information regarding use of this OFDM PHY are in Annex D and Annex E.

18.1.2 Scope

Subclause 18.1 describes the PHY services provided to the IEEE 802.11 WLAN MAC by the OFDM PHY. The OFDM PHY consists of two protocol functions, as follows:

a) A PHY convergence function, which adapts the capabilities of the PMD system to the PHY service. This function is supported by the PLCP, which defines a method of mapping the IEEE 802.11 PSDUs into a framing format suitable for sending and receiving user data and management information between two or more STAs using the associated PMD system.

b) A PMD system whose function defines the characteristics and method of transmitting and receiving data through a WM between two or more STAs, each using the OFDM system.

18.1.3 OFDM PHY functions

18.1.3.1 General

The OFDM PHY architecture is depicted in the reference model shown in Figure 4-14 (in 4.9). The OFDM PHY contains three functional entities: the PMD function, the PHY convergence function, and the layer management function. Each of these functions is described in detail in 18.1.3.2 to 18.1.3.5.

The OFDM PHY service is provided to the MAC through the PHY service primitives described in Clause 7.

18.1.3.2 PLCP sublayer

In order to allow the IEEE 802.11 MAC to operate with minimum dependence on the PMD sublayer, a PHY convergence sublayer is defined. This function simplifies the PHY service interface to the IEEE 802.11 MAC services.
18.1.3.3 PMD sublayer

The PMD sublayer provides a means to send and receive data between two or more STAs. This clause is concerned with PHYs using OFDM modulation.

18.1.3.4 PLME

The PLME performs management of the local PHY functions in conjunction with the MLME.

18.1.3.5 Service specification method

The models represented by figures and state diagrams are intended to be illustrations of the functions provided. It is important to distinguish between a model and a real implementation. The models are optimized for simplicity and clarity of presentation; the actual method of implementation is left to the discretion of the IEEE 802.11 OFDM-PHY-compliant developer.

The service of a layer or sublayer is the set of capabilities that it offers to a user in the next higher layer (or sublayer). Abstract services are specified here by describing the service primitives and parameters that characterize each service. This definition is independent of any particular implementation.

18.2 OFDM PHY specific service parameter list

18.2.1 Introduction

The architecture of the IEEE 802.11 MAC is intended to be PHY independent. Some PHY implementations require medium management state machines running in the MAC sublayer in order to meet certain PMD requirements. These PHY-dependent MAC state machines reside in a sublayer defined as the MLME. In certain PMD implementations, the MLME may need to interact with the PLME as part of the normal PHY-SAP primitives. These interactions are defined by the PLME parameter list currently defined in the PHY service primitives as TXVECTOR and RXVECTOR. The list of these parameters, and the values they may represent, are defined in the specific PHY specifications for each PMD. Subclause 18.2 addresses the TXVECTOR and RXVECTOR for the OFDM PHY.

18.2.2 TXVECTOR parameters

18.2.2.1 General

The parameters in Table 18-1 are defined as part of the TXVECTOR parameter list in the PHY-TXSTART.request primitive.

18.2.2.2 TXVECTOR LENGTH

The allowed values for the LENGTH parameter are in the range of 1 to 4095. This parameter is used to indicate the number of octets in the MPDU which the MAC is currently requesting the PHY to transmit. This value is used by the PHY to determine the number of octet transfers that will occur between the MAC and the PHY after receiving a request to start the transmission.

18.2.2.3 TXVECTOR DATARATE

The DATARATE parameter describes the bit rate at which the PLCP shall transmit the PSDU. Its value takes any of the rates defined in Table 18-1. Data rates of 6, 12, and 24 Mb/s shall be supported for 20 MHz channel spacing, data rates of 3, 6, and 12 Mb/s shall be supported for 10 MHz channel spacing, and data rates of 1.5, 3, and 6 Mb/s shall be supported for 5 MHz channel spacing; other rates may also be supported.

</tr>
</tbody>
</table>

18.2.2.4 TXVECTOR SERVICE

The SERVICE parameter consists of 7 null bits used for the scrambler initialization and 9 null bits reserved for future use.

18.2.2.5 TXVECTOR TXPWR_LEVEL

The allowed values for the TXPWR_LEVEL parameter are in the range from 1 to 8. This parameter is used to indicate which of the available TxPowerLevel attributes defined in the MIB shall be used for the current transmission.

18.2.2.6 TIME_OF_DEPARTURE_REQUESTED

The allowed values are false or true. A parameter value of true indicates that the MAC sublayer is requesting that the PLCP entity provides measurement of when the first frame energy is sent by the transmitting port and reporting within the PHY-TXSTART.confirm(TXSTATUS) primitive. A parameter value of false indicates that the MAC sublayer is requesting that the PLCP entity not provide time of departure measurement nor reporting in the PHY-TXSTART.confirm(TXSTATUS) primitive.

18.2.3 RXVECTOR parameters

18.2.3.1 General

The parameters listed in Table 18-2 are defined as part of the RXVECTOR parameter list in the PHY-RXSTART.indication primitive.

</tr>
</tbody>
</table>

**NOTE**—Parameter is present only when dot11RadioMeasurementActivated is true.

### 18.2.3.2 RXVECTOR LENGTH

The allowed values for the LENGTH parameter are in the range from 1–4095. This parameter is used to indicate the value contained in the LENGTH field which the PLCP has received in the PLCP header. The MAC and PLCP use this value to determine the number of octet transfers that will occur between the two sublayers during the transfer of the received PSDU.

### 18.2.3.3 RXVECTOR RSSI

The allowed values for the RSSI parameter are in the range from 0 to RSSI maximum. This parameter is a measure by the PHY of the energy observed at the antenna used to receive the current PPDU. RSSI shall be measured during the reception of the PLCP preamble. RSSI is intended to be used in a relative manner, and it shall be a monotonically increasing function of the received power.
18.2.3.4 DATARATE

DATARATE shall represent the data rate at which the current PPDU was received. The allowed values of the DATARATE are 6, 9, 12, 18, 24, 36, 48, or 54 Mb/s for 20 MHz channel spacing; 3, 4.5, 6, 9, 12, 18, 24, or 27 Mb/s for 10 MHz channel spacing; and 1.5, 2.25, 3, 4.5, 6, 9, 12, or 13.5 Mb/s for 5 MHz channel spacing.

18.2.3.5 SERVICE

The SERVICE field shall be null.

18.2.3.6 RIVATECTOR RCPI

The allowed values for the RCPI parameter are in the range from 0 to 255, as defined in 18.3.10.7. This parameter is a measure by the PHY of the received channel power. RCPI indications of 8 bits are supported. RCPI shall be measured over the entire received frame or by other equivalent means that meet the specified accuracy.

18.2.4 TXSTATUS parameters

18.2.4.1 General

The parameters listed in Table 18-3 are defined as part of the TXSTATUS parameter list in the PHY-TXSTART.confirm service primitive.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Associated primitive</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>TIME_OF_DEPARTURE</td>
<td>PHY-TXSTART.confirm</td>
<td>0 to (2^{32} - 1). The locally measured time when the first frame energy is sent by the transmitting port, in units equal to (1/) TIME_OF_DEPARTURE_ClockRate. This parameter is present only if TIME_OF_DEPARTURE_REQUESTED is true in the corresponding request.</td>
</tr>
<tr>
<td>TIME_OF_DEPARTURE_ClockRate</td>
<td>PHY-TXSTART.confirm</td>
<td>0 to (2^{16} - 1). The clock rate, in units of MHz, is used to generate the TIME_OF_DEPARTURE value. This parameter is present only if TIME_OF_DEPARTURE_REQUESTED is true in the corresponding request.</td>
</tr>
<tr>
<td>TX_START_OF_FRAME_OFFSET</td>
<td>PHY-TXSTART.confirm</td>
<td>0 to (2^{32} - 1). An estimate of the offset (in 10 ns units) from the point in time at which the start of the preamble corresponding to the frame was transmitted at the transmit antenna port to the point in time at which this primitive is issued to the MAC.</td>
</tr>
</tbody>
</table>

18.2.4.2 TXSTATUS TIME_OF_DEPARTURE

The allowed values for the TIME_OF_DEPARTURE parameter are integers in the range of 0 to \(2^{32} - 1\). This parameter is used to indicate when the first frame energy is sent by the transmitting port in units equal to \(1/\) TIME_OF_DEPARTURE_ClockRate. TIME_OF_DEPARTURE may be included in the transmitted frame.
in order for recipients on multiple channels to determine the time differences of air propagation times between transmitter and recipients and hence to compute the location of the transmitter.

18.2.4.3 TXSTATUS TIME_OF_DEPARTURE_ClockRate

TIME_OF_DEPARTURE_ClockRate indicates the clock rate used for TIME_OF_DEPARTURE.

18.3 OFDM PLCP sublayer

18.3.1 Introduction

Subclause 18.3 provides a convergence procedure in which PSDUs are converted to and from PPDUs. During transmission, the PSDU shall be provided with a PLCP preamble and header to create the PPDU. At the receiver, the PLCP preamble and header are processed to aid in demodulation and delivery of the PSDU.

18.3.2 PLCP frame format

18.3.2.1 General

Figure 18-1 shows the format for the PPDU including the OFDM PLCP preamble, OFDM PLCP header, PSDU, tail bits, and pad bits. The PLCP header contains the following fields: LENGTH, RATE, a reserved bit, an even parity bit, and the SERVICE field. In terms of modulation, the LENGTH, RATE, reserved bit, and parity bit (with 6 zero tail bits appended) constitute a separate single OFDM symbol, denoted SIGNAL, which is transmitted with the most robust combination of BPSK modulation and a coding rate of $R = 1/2$. The SERVICE field of the PLCP header and the PSDU (with 6 zero tail bits and pad bits appended), denoted as DATA, are transmitted at the data rate described in the RATE field and may constitute multiple OFDM symbols. The tail bits in the SIGNAL symbol enable decoding of the RATE and LENGTH fields immediately after the reception of the tail bits. The RATE and LENGTH fields are required for decoding the DATA part of the packet. In addition, the CCA mechanism is augmented by predicting the duration of the packet from the contents of the RATE and LENGTH fields, even if the data rate is not supported by the STA. Each of these fields is described in detail in 18.3.3, 18.3.4, and 18.3.5.

![Figure 18-1—PPDU frame format](image)

18.3.2.2 Overview of the PPDU encoding process

The encoding process is composed of many detailed steps, which are described fully in later subclauses, as noted below. The following overview intends to facilitate understanding the details of the convergence procedure:
a) Produce the PLCP Preamble field, composed of 10 repetitions of a “short training sequence” (used for AGC convergence, diversity selection, timing acquisition, and coarse frequency acquisition in the receiver) and two repetitions of a “long training sequence” (used for channel estimation and fine frequency acquisition in the receiver), preceded by a guard interval (GI). Refer to 18.3.3 for details.

b) Produce the PLCP header field from the RATE, LENGTH, and SERVICE fields of the TXVECTOR by filling the appropriate bit fields. The RATE and LENGTH fields of the PLCP header are encoded by a convolutional code at a rate of $R = 1/2$, and are subsequently mapped onto a single BPSK encoded OFDM symbol, denoted as the SIGNAL symbol. In order to facilitate a reliable and timely detection of the RATE and LENGTH fields, 6 zero tail bits are inserted into the PLCP header. The encoding of the SIGNAL field into an OFDM symbol follows the same steps for convolutional encoding, interleaving, BPSK modulation, pilot insertion, Fourier transform, and prepending a GI as described subsequently for data transmission with BPSK-OFDM modulated at coding rate 1/2. The contents of the SIGNAL field are not scrambled. Refer to 18.3.4 for details.

c) Calculate from RATE field of the TXVECTOR the number of data bits per OFDM symbol ($N_{DBPS}$), the coding rate ($R$), the number of bits in each OFDM subcarrier ($N_{BPCS}$), and the number of coded bits per OFDM symbol ($N_{CBPS}$). Refer to 18.3.2.3 for details.

d) Append the PSDU to the SERVICE field of the TXVECTOR. Extend the resulting bit string with zero bits (at least 6 bits) so that the resulting length is a multiple of $N_{DBPS}$. The resulting bit string constitutes the DATA part of the packet. Refer to 18.3.5.4 for details.

e) Initiate the scrambler with a pseudorandom nonzero seed, generate a scrambling sequence, and XOR it with the extended string of data bits. Refer to 18.3.5.5 for details.

f) Replace the six scrambled zero bits following the data with six nonscrambled zero bits. (Those bits return the convolutional encoder to the zero state and are denoted as tail bits.) Refer to 18.3.5.3 for details.

g) Encode the extended, scrambled data string with a convolutional encoder ($R = 1/2$). Omit (puncture) some of the encoder output string (chosen according to “puncturing pattern”) to reach the desired “coding rate.” Refer to 18.3.5.6 for details.

h) Divide the encoded bit string into groups of $N_{CBPS}$ bits. Within each group, perform an “interleaving” (reordering) of the bits according to a rule corresponding to the desired RATE. Refer to 18.3.5.7 for details.

i) Divide the resulting coded and interleaved data string into groups of $N_{BPCS}$ bits. For each of the bit groups, convert the bit group into a complex number according to the modulation encoding tables. Refer to 18.3.5.8 for details.

j) Divide the complex number string into groups of 48 complex numbers. Each such group is associated with one OFDM symbol. In each group, the complex numbers are numbered 0 to 47 and mapped hereafter into OFDM subcarriers numbered –26 to –22, –20 to –8, –6 to –1, 1 to 6, 8 to 20, and 22 to 26. The subcarriers –21, –7, 7, and 21 are skipped and, subsequently, used for inserting pilot subcarriers. The 0 subcarrier, associated with center frequency, is omitted and filled with the value 0. Refer to 18.3.5.10 for details.

k) Four subcarriers are inserted as pilots into positions –21, –7, 7, and 21. The total number of the subcarriers is 52 (48 + 4). Refer to 18.3.5.9 for details.

l) For each group of subcarriers –26 to 26, convert the subcarriers to time domain using inverse Fourier transform. Prepend to the Fourier-transformed waveform a circular extension of itself thus forming a GI, and truncate the resulting periodic waveform to a single OFDM symbol length by applying time domain windowing. Refer to 18.3.5.10 for details.

m) Append the OFDM symbols one after another, starting after the SIGNAL symbol describing the RATE and LENGTH fields. Refer to 18.3.5.10 for details.
n) Up-convert the resulting “complex baseband” waveform to an RF according to the center frequency of the desired channel and transmit. Refer to 18.3.2.5 and 18.3.8.2 for details.

An illustration of the transmitted frame and its parts appears in Figure 18-4 (in 18.3.3).

18.3.2.3 Modulation-dependent parameters

The modulation parameters dependent on the data rate used shall be set according to Table 18-4.

<table>

### 18.3.2.5 Mathematical conventions in the signal descriptions

The transmitted signals are described in a complex baseband signal notation. The actual transmitted signal is related to the complex baseband signal by the following relation:

\[ r_{(RF)}(t) = \text{Re} \{ r(t) \exp(j2\pi f_c t) \} \]  \hspace{1cm} (18-1)

where
- \text{Re}(.) represents the real part of a complex variable
- \( f_c \) denotes the carrier center frequency

The transmitted baseband signal is composed of contributions from several OFDM symbols.

\[ r_{\text{PACKET}}(t) = r_{\text{PREAMBLE}}(t) + r_{\text{SIGNAL}}(t - t_{\text{SIGNAL}}) + r_{\text{DATA}}(t - t_{\text{DATA}}) \]  \hspace{1cm} (18-2)

The subframes of which Equation (18-2) are composed are described in 18.3.3, 18.3.4, and 18.3.5.10. The time offsets \( t_{\text{SUBFRAME}} \) determine the starting time of the corresponding subframe; \( t_{\text{SIGNAL}} \) is equal to 16 \( \mu s \) for 20 MHz channel spacing, 32 \( \mu s \) for 10 MHz channel spacing, and 64 \( \mu s \) for 5 MHz channel spacing, and \( t_{\text{DATA}} \) is equal to 20 \( \mu s \) for 20 MHz channel spacing, 40 \( \mu s \) for 10 MHz channel spacing, and 80 \( \mu s \) for 5 MHz channel spacing.

All the subframes of the signal are constructed as an inverse Fourier transform of a set of coefficients, \( C_k \), with \( C_k \) defined later as data, pilots, or training symbols in 18.3.3 to 18.3.5.

\[ r_{\text{SUBFRAME}}(t) = w_{\text{SUBFRAME}}(t) \sum_{k=-N_{\text{FFT}}/2}^{N_{\text{FFT}}/2} C_k \exp(j2\pi k\Delta)(t - T_{\text{GUARD}}) \]  \hspace{1cm} (18-3)

The parameters \( \Delta_f \) and \( N_{\text{FFT}} \) are described in Table 18-5. The resulting waveform is periodic with a period of \( T_{\text{FFT}} = 1/\Delta_f \). Shifting the time by \( T_{\text{GUARD}} \) creates the “circular prefix” used in OFDM to avoid ISI from the
previous frame. Three kinds of $T_{GUARD}$ are defined: for the short training sequence ($= 0 \mu s$), for the long training sequence ($= T_{GI}$), and for data OFDM symbols ($= T_{GI}$). (Refer to Table 18-5.) The boundaries of the subframe are set by a multiplication by a time-windowing function, $w_{SUBFRAME}(t)$, which is defined as a rectangular pulse, $w_{T}(t)$, of duration $T$, accepting the value $T_{SUBFRAME}$. The time-windowing function, $w_{T}(t)$, depending on the value of the duration parameter, $T$, may extend over more than one period, $T_{FFT}$. In particular, window functions that extend over multiple periods of the FFT are utilized in the definition of the preamble. Figure 18-2 illustrates the possibility of extending the windowing function over more than one period, $T_{FFT}$, and additionally shows smoothed transitions by application of a windowing function, as exemplified in Equation (18-4). In particular, window functions that extend over multiple periods of the FFT are utilized in the definition of the preamble.

\[
w_{T}(t) = \begin{cases} 
\sin\left(\frac{\pi}{2}(0.5 + t/T_{TR})\right) & (-T_{TR}/2 < t < T_{TR}/2) \\
1 & (T_{TR}/2 < t < T - T_{TR}/2) \\
\sin\left(\frac{\pi}{2}(0.5 - (t - T)/T_{TR})\right) & (T - T_{TR}/2 < t < T + T_{TR}/2)
\end{cases}
\] (18-4)

In the case of vanishing $T_{TR}$, the windowing function degenerates into a rectangular pulse of duration $T$. The normative specifications of generating the transmitted waveforms shall utilize the rectangular pulse shape. In implementation, higher $T_{TR}$ is typically implemented in order to smooth the transitions between the consecutive subsections. This creates a small overlap between them, of duration $T_{TR}$, as shown in Figure 18-2. The transition time, $T_{TR}$, is about 100 ns. Smoothing the transition is required in order to reduce the spectral sidelobes of the transmitted waveform. However, the binding requirements are the spectral mask and modulation accuracy requirements, as detailed in 18.3.9.3 and 18.3.9.7. Time domain windowing, as described here, is just one way to achieve those objectives. The implementer may use other methods to achieve the same goal, such as frequency domain filtering. Therefore, the transition shape and duration of the transition are informative parameters.

Figure 18-2—Illustration of OFDM frame with cyclic extension and windowing for (a) single reception or (b) two receptions of the FFT period.
18.3.2.6 Discrete time implementation considerations

The following descriptions of the discrete time implementation are informational.

In a typical implementation, the windowing function is represented in discrete time. As an example, when a windowing function with parameters $T = 4.0$ μs and $T_{TR} = 100$ ns is applied, and the signal is sampled at 20 Msample/s, it becomes

$$w_T[n] = w_T(nT_s) = \begin{cases} 1 & 1 \leq n \leq 79 \\ 0.5 & 0, 80 \\ 0 & otherwise \end{cases}$$

(18-5)

The common way to implement the inverse Fourier transform, as shown in Equation (18-3), is by an IFFT algorithm. If, for example, a 64-point IFFT is used, the coefficients 1 to 26 are mapped to the same numbered IFFT inputs, while the coefficients –26 to –1 are copied into IFFT inputs 38 to 63. The rest of the inputs, 27 to 37 and the 0 (dc) input, are set to 0. This mapping is illustrated in Figure 18-3. After performing an IFFT, the output is cyclically extended to the desired length.

![Figure 18-3—Inputs and outputs of inverse Fourier transform](image)

18.3.3 PLCP preamble (SYNC)

The PLCP Preamble field is used for synchronization. It consists of 10 short symbols and two long symbols that are shown in Figure 18-4 and described in this subclause. The timings described in this subclause and shown in Figure 18-4 are for 20 MHz channel spacing. They are doubled for half-clocked (i.e., 10 MHz) channel spacing and are quadrupled for quarter-clocked (i.e., 5 MHz) channel spacing.

![Figure 18-4—OFDM training structure](image)
Figure 18-4 shows the OFDM training structure (PLCP preamble), where \( t_1 \) to \( t_{10} \) denote short training symbols and \( T_1 \) and \( T_2 \) denote long training symbols. The PLCP preamble is followed by the SIGNAL field and DATA. The total training length is \( 16 \mu s \). The dashed boundaries in the figure denote repetitions due to the periodicity of the inverse Fourier transform.

A short OFDM training symbol consists of 12 subcarriers, which are modulated by the elements of the sequence \( S \), given by

\[
S_{-26, 26} = \sqrt{\frac{13}{6}} \times \{0, 0, 1+j, 0, 0, 0, -1-j, 0, 0, 0, 1+j, 0, 0, 0, -1-j, 0, 0, 0, 1+j, 0, 0, 0, 0, 0, 0, 0, -1-j, 0, 0, 0, -1-j, 0, 0, 0, 1+j, 0, 0, 0, 1+j, 0, 0, 0, 1+j \} \quad (18-6)
\]

The multiplication by a factor of \( \sqrt{\frac{13}{6}} \) is in order to normalize the average power of the resulting OFDM symbol, which utilizes 12 out of 52 subcarriers.

The signal shall be generated according to the following equation:

\[
r_{SHORT}(t) = w_{SHORT}(t) \sum_{k = -N_{syf}/2}^{N_{syf}/2} S_k \exp(j2\pi k\Delta f t) \quad (18-7)
\]

The fact that only spectral lines of \( S_{-26, 26} \) with indices that are a multiple of 4 have nonzero amplitude results in a periodicity of \( T_{FFT}/4 = 0.8 \mu s \). The interval \( T_{SHORT} \) is equal to ten \( 0.8 \mu s \) periods (i.e., 8 \( \mu s \)).

Generation of the short training sequence is illustrated in Table L-2.

A long OFDM training symbol consists of 53 subcarriers (including the value 0 at dc), which are modulated by the elements of the sequence \( L \), given by

\[
L_{-26, 26} = \{1, 1, -1, 1, 1, -1, 1, 1, 1, 1, 1, -1, 1, 1, -1, 1, 1, -1, 1, 1, 1, 1, 1, 0, 1, -1, -1, 1, -1, 1, -1, -1, -1, -1, 1, -1, -1, -1, -1, -1, 1, 1, -1, -1, 1, 1, 1, 1\} \quad (18-8)
\]

A long OFDM training symbol shall be generated according to the following equation:

\[
r_{LONG}(t) = w_{LONG}(t) \sum_{k = -N_{syf}/2}^{N_{syf}/2} L_k \exp(j2\pi k\Delta f(t - T_{G12})) \quad (18-9)
\]

where

\[ T_{G12} = 1.6 \mu s \]

Two periods of the long sequence are transmitted for improved channel estimation accuracy, yielding \( T_{LONG} = 1.6 + 2 \times 3.2 = 8 \mu s \).

An illustration of the long training sequence generation is given in Table L-5.

The sections of short repetitions and long repetitions shall be concatenated to form the preamble

\[
r_{PREAMBLE}(t) = r_{SHORT}(t) + r_{LONG}(t - T_{SHORT}) \quad (18-10)
\]
18.3.4 SIGNAL field

18.3.4.1 General

The OFDM training symbols shall be followed by the SIGNAL field, which contains the RATE and the LENGTH fields of the TXVECTOR. The RATE field conveys information about the type of modulation and the coding rate as used in the rest of the packet. The encoding of the SIGNAL single OFDM symbol shall be performed with BPSK modulation of the subcarriers and using convolutional coding at R = 1/2. The encoding procedure, which includes convolutional encoding, interleaving, modulation mapping processes, pilot insertion, and OFDM modulation, follows the steps described in 18.3.5.6, 18.3.5.7, and 18.3.5.9, as used for transmission of data with BPSK-OFDM modulated at coding rate 1/2. The contents of the SIGNAL field are not scrambled.

The SIGNAL field shall be composed of 24 bits, as illustrated in Figure 18-5. The four bits 0 to 3 shall encode the RATE. Bit 4 shall be reserved for future use. Bits 5–16 shall encode the LENGTH field of the TXVECTOR, with the LSB being transmitted first.

The process of generating the SIGNAL OFDM symbol is illustrated in L.1.4.

18.3.4.2 RATE field

The bits R1–R4 shall be set, dependent on RATE, according to the values in Table 18-6.

<table>

</tr>
</tbody>
</table>

Table 18-6—Contents of the SIGNAL field
18.3.4.3 PLCP LENGTH field

The PLCP LENGTH field shall be an unsigned 12-bit integer that indicates the number of octets in the PSDU that the MAC is currently requesting the PHY to transmit. This value is used by the PHY to determine the number of octet transfers that will occur between the MAC and the PHY after receiving a request to start transmission. The transmitted value shall be determined from the LENGTH parameter in the TXVECTOR issued with the PHY-TXSTART.request primitive described in 7.3.5.5. The LSB shall be transmitted first in time. This field shall be encoded by the convolutional encoder described in 18.3.5.6.

18.3.4.4 Parity (P), Reserved (R), and SIGNAL TAIL fields

Bit 4 is reserved. It shall be set to 0 on transmit and ignored on receive. Bit 17 shall be a positive parity (even parity) bit for bits 0–16. The bits 18–23 constitute the SIGNAL TAIL field, and all 6 bits shall be set to 0.

18.3.5 DATA field

18.3.5.1 General

The DATA field contains the SERVICE field, the PSDU, the TAIL bits, and the PAD bits, if needed, as described in 18.3.5.3 and 18.3.5.4. All bits in the DATA field are scrambled, as described in 18.3.5.5.

18.3.5.2 SERVICE field

The IEEE 802.11 SERVICE field has 16 bits, which shall be denoted as bits 0–15. The bit 0 shall be transmitted first in time. The bits from 0–6 of the SERVICE field, which are transmitted first, are set to 0s and are used to synchronize the descrambler in the receiver. The remaining 9 bits (7–15) of the SERVICE field shall be reserved for future use. All reserved bits shall be set to 0. Refer to Figure 18-6.

```
<table>

<td>1</td>
</tr>
</tbody>
</table>
```

R: Reserved

Transmit Order

Figure 18-6—SERVICE field bit assignment

18.3.5.3 PPDU TAIL field

The PPDU TAIL field shall be six bits of 0, which are required to return the convolutional encoder to the zero state. This procedure improves the error probability of the convolutional decoder, which relies on future bits when decoding and which may be not be available past the end of the message. The PLCP tail bit field shall be produced by replacing six scrambled zero bits following the message end with six nonscrambled zero bits.

18.3.5.4 Pad bits (PAD)

The number of bits in the DATA field shall be a multiple of $N_{CBPS}$, the number of coded bits in an OFDM symbol (48, 96, 192, or 288 bits). To achieve that, the length of the message is extended so that it becomes a multiple of $N_{DBPS}$, the number of data bits per OFDM symbol. At least 6 bits are appended to the message, in order to accommodate the TAIL bits, as described in 18.3.5.3. The number of OFDM symbols, $N_{SYM}$; the
number of bits in the DATA field, \( N_{\text{DATA}} \); and the number of pad bits, \( N_{\text{PAD}} \), are computed from the length of the PSDU (LENGTH) as follows:

\[
N_{\text{SYM}} = \text{Ceiling} \left( \frac{(16 + 8 \times \text{LENGTH} + 6)}{N_{\text{DBPS}}} \right)
\]  
\[
N_{\text{DATA}} = N_{\text{SYM}} \times N_{\text{DBPS}}
\]  
\[
N_{\text{PAD}} = N_{\text{DATA}} - (16 + 8 \times \text{LENGTH} + 6)
\]

The function Ceiling(.) is a function that returns the smallest integer value greater than or equal to its argument value. The appended bits (“pad bits”) are set to 0 and are subsequently scrambled with the rest of the bits in the DATA field.

An example of a DATA field that contains the SERVICE field, DATA, tail, and pad bits is given in L.1.5.1.

**18.3.5.5 PLCP DATA scrambler and descrambler**

The DATA field, composed of SERVICE, PSDU, tail, and pad parts, shall be scrambled with a length-127 frame-synchronous scrambler. The octets of the PSDU are placed in the transmit serial bit stream, bit 0 first and bit 7 last. The frame synchronous scrambler uses the generator polynomial \( S(x) \) as follows, and is illustrated in Figure 18-7:

\[
S(x) = x^7 + x^4 + 1
\]

The 127-bit sequence generated repeatedly by the scrambler shall be (leftmost used first), 00001110 11110010 11001001 00000010 01001110 01101110 10110110 00011000 11010100 11100111 10110100 00101010 11111010 01010001 10111000 11111111, when the all ones initial state is used. The same scrambler is used to scramble transmit data and to descramble receive data. When transmitting, the initial state of the scrambler shall be set to a pseudorandom nonzero state. The seven LSBs of the SERVICE field shall be set to all zeros prior to scrambling to enable estimation of the initial state of the scrambler in the receiver.

An example of the scrambler output is illustrated in L.1.5.2.

**18.3.5.6 Convolutional encoder**

The DATA field, composed of SERVICE, PSDU, tail, and pad parts, shall be coded with a convolutional encoder of coding rate \( R = 1/2, 2/3, \) or \( 3/4 \), corresponding to the desired data rate. The convolutional encoder shall use the industry-standard generator polynomials, \( g_0 = 133_8 \) and \( g_1 = 171_8 \), of rate \( R = 1/2 \), as shown in Figure 18-8. The bit denoted as “A” shall be output from the encoder before the bit denoted as “B.” Higher rates are derived from it by employing “puncturing.” Puncturing is a procedure for omitting some of the
encoded bits in the transmitter (thus reducing the number of transmitted bits and increasing the coding rate) and inserting a dummy “zero” metric into the convolutional decoder on the receive side in place of the omitted bits. The puncturing patterns are illustrated in Figure 18-9. Decoding by the Viterbi algorithm is recommended.

An example of encoding operation is shown in L.1.6.1.

![Convolutional encoder (k = 7)](image)

**Figure 18-8—Convolutional encoder (k = 7)**

### 18.3.5.7 Data interleaving

All encoded data bits shall be interleaved by a block interleaver with a block size corresponding to the number of bits in a single OFDM symbol, $N_{CBPS}$. The interleaver is defined by a two-step permutation. The first permutation ensures that adjacent coded bits are mapped onto nonadjacent subcarriers. The second ensures that adjacent coded bits are mapped alternately onto less and more significant bits of the constellation and, thereby, long runs of low reliability (LSB) bits are avoided.

The index of the coded bit before the first permutation shall be denoted by $k$; $i$ shall be the index after the first and before the second permutation; and $j$ shall be the index after the second permutation, just prior to modulation mapping.

The first permutation is defined by the rule

$$i = (N_{CBPS}/16) \cdot (k \mod 16) + \text{Floor}(k/16) \quad k = 0,1,\ldots,N_{CBPS} - 1 \quad (18-15)$$

The function Floor (.) denotes the largest integer not exceeding the parameter.

The second permutation is defined by the rule

$$j = s \times \text{Floor}(i/s) + (i + N_{CBPS} - \text{Floor}(16 \times i/N_{CBPS}) \mod s \quad i = 0,1,\ldots,N_{CBPS} - 1 \quad (18-16)$$

The value of $s$ is determined by the number of coded bits per subcarrier, $N_{BPSC}$, according to

$$s = \max(N_{BPSC}/2, 1) \quad (18-17)$$

The deinterleaver, which performs the inverse relation, is also defined by two permutations.
Figure 18-9—Example of the bit-stealing and bit-insertion procedure (r = 3/4, 2/3)
IEEE Std 802.11-2012 LOCAL AND METROPOLITAN AREA NETWORKS—SPECIFIC REQUIREMENTS

Here the index of the original received bit before the first permutation shall be denoted by $j$; $i$ shall be the index after the first and before the second permutation; and $k$ shall be the index after the second permutation, just prior to delivering the coded bits to the convolutional (Viterbi) decoder.

The first permutation is defined by the rule

$$i = s \times \text{Floor}(j/s) + (j + \text{Floor}(16 \times j/N_{CBPS})) \mod s \quad j = 0, 1, \ldots, N_{CBPS} - 1 \quad (18-18)$$

where

$$s$$

is defined in Equation (18-17).

This permutation is the inverse of the permutation described in Equation (18-16).

The second permutation is defined by the rule

$$k = 16 \times i - (N_{CBPS} - 1)\text{Floor}(16 \times i/N_{CBPS}) \quad i = 0, 1, \ldots, N_{CBPS} - 1 \quad (18-19)$$

This permutation is the inverse of the permutation described in Equation (18-15).

An example of interleaving operation is illustrated in L.1.6.2.

18.3.5.8 Subcarrier modulation mapping

The OFDM subcarriers shall be modulated by using BPSK, QPSK, 16-QAM, or 64-QAM, depending on the RATE requested. The encoded and interleaved binary serial input data shall be divided into groups of $N_{BPSC}$ (1, 2, 4, or 6) bits and converted into complex numbers representing BPSK, QPSK, 16-QAM, or 64-QAM constellation points. The conversion shall be performed according to Gray-coded constellation mappings, illustrated in Figure 18-10, with the input bit, $b_0$, being the earliest in the stream. The output values, $d$, are formed by multiplying the resulting $(I+jQ)$ value by a normalization factor $K_{MOD}$, as described in Equation (18-20).

$$d = (I + jQ) \times K_{MOD} \quad (18-20)$$

The normalization factor, $K_{MOD}$, depends on the base modulation mode, as prescribed in Table 18-7. Note that the modulation type can be different from the start to the end of the transmission, as the signal changes from SIGNAL to DATA, as shown in Figure 18-1. The purpose of the normalization factor is to achieve the same average power for all mappings. In practical implementations, an approximate value of the normalization factor may be used, as long as the device conforms with the modulation accuracy requirements described in 18.3.9.7.

18.3.5.9 Pilot subcarriers

In each OFDM symbol, four of the subcarriers are dedicated to pilot signals in order to make the coherent detection robust against frequency offsets and phase noise. These pilot signals shall be put in subcarriers –21, –7, 7, and 21. The pilots shall be BPSK modulated by a pseudo-binary sequence to prevent the generation of spectral lines. The contribution of the pilot subcarriers to each OFDM symbol is described in 18.3.5.10.

18.3.5.10 OFDM modulation

The stream of complex numbers is divided into groups of $N_{SD} = 48$ complex numbers. This shall be denoted by writing the complex number $d_{k,n}$, which corresponds to subcarrier $k$ of OFDM symbol $n$, as follows:

$$d_{k,n} = d_{k + N_{SD} \times n}$$

$k = 0, ... N_{SD} - 1$, $n = 0, ... N_{SYM} - 1$ (18-21)

The number of OFDM symbols, $N_{SYM}$, was introduced in 18.3.5.4.

An OFDM symbol, $r_{DATA,n}(t)$, is defined as

$$r_{DATA,n}(t) = w_{TSYM}(t) \sum_{k=0}^{N_{SD}-1} d_{k,n} \exp((j2\pi M(k)\Delta F(t - T_{GI}))$$

$$+ p_{n+1} \sum_{k=-N_{SF}/2}^{N_{SF}/2} P_k \exp(j2\pi k\Delta F(t - T_{GI}))$$

where the function, $M(k)$, defines a mapping from the logical subcarrier number 0 to 47 into frequency offset index –26 to 26, while skipping the pilot subcarrier locations and the 0th (dc) subcarrier.

$$M(k) = \begin{cases} 
  k - 26 & 0 \leq k \leq 4 \\
  k - 25 & 5 \leq k \leq 17 \\
  k - 24 & 18 \leq k \leq 23 \\
  k - 23 & 24 \leq k \leq 29 \\
  k - 22 & 30 \leq k \leq 42 \\
  k - 21 & 43 \leq k \leq 47 
\end{cases}$$

(18-23)

The contribution of the pilot subcarriers for the $n^{th}$ OFDM symbol is produced by inverse Fourier transform of sequence $P$, given by

$$P_{-26, 26} = \{0, 0, 0, 0, 0, 0, 1, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, -1, 0, 0, 0, 0\}$$

(18-24)
The polarity of the pilot subcarriers is controlled by the sequence, $p_n$, which is a cyclic extension of the 127 elements sequence and is given by

$$p_{0..126} = \{1,1,1,1, -1,-1,-1,1, 1,1,1,1, -1,-1,-1,1, 1,1,1,1, -1,-1,-1,1, -1,-1,-1,1, 1,1,1,1, 1,1,-1,1, -1,-1,-1,1, -1,-1,-1,1, 1,1,1,1, 1,1,-1,1, -1,-1,-1,1, -1,-1,-1\}$$

The sequence $p_0$ is generated by the scrambler defined by Figure 18-7 when the all ones initial state is used, and by replacing all 1s with –1 and all 0s with 1. Each sequence element is used for one OFDM symbol. The first element, $p_0$, multiplies the pilot subcarriers of the SIGNAL symbol, while the elements from $p_1$ on are used for the DATA symbols.

The subcarrier frequency allocation is shown in Figure 18-11. To avoid difficulties in D/A and A/D converter offsets and carrier feedthrough in the RF system, the subcarrier falling at DC (0th subcarrier) is not used.

The concatenation of $N_{SYM}$ OFDM symbols is written as

$$r_{DATA}(t) = \sum_{n=0}^{N_{SYM}-1} r_{DATA,n}(t-nT_{SYM})$$

An example of mapping into symbols is shown in L.1.6.3, as well as the scrambling of the pilot signals (see L.1.7). The final output of these operations is also shown in L.1.8.

18.3.6 CCA

PLCP shall provide the capability to perform CCA and report the result to the MAC. The CCA mechanism shall detect a “medium busy” condition with requirements specified in 18.3.10.6 and 18.3.12. This medium status report is indicated by the PHY_CCA.indication primitive.

18.3.7 PLCP data modulation and modulation rate change

The PLCP preamble shall be transmitted using an OFDM modulated fixed waveform. The IEEE 802.11 SIGNAL field, BPSK-OFDM modulated with coding rate 1/2, shall indicate the modulation and coding rate that shall be used to transmit the MPDU. The transmitter (receiver) shall initiate the modulation (demodulation) constellation and the coding rate according to the RATE indicated in the SIGNAL field. The MPDU transmission rate shall be set by the DATARATE parameter in the TXVECTOR, issued with the PHY-TXSTART.request primitive described in 18.2.2.
18.3.8 PMD operating specifications (general)

18.3.8.1 General

General specifications for the BPSK OFDM, QPSK OFDM, 16-QAM OFDM, and 64-QAM OFDM PMD sublayers are provided in 18.3.8.2 to 18.3.8.8. These specifications apply to both the receive and transmit functions and general operation of the OFDM PHY.

18.3.8.2 Outline description

The general block diagram of the transmitter and receiver for the OFDM PHY is shown in Figure 18-12. Major specifications for the OFDM PHY are listed in Table 18-12.

*aRefer to 18.3.2.5.*
18.3.8.3 Regulatory requirements

WLANs implemented in accordance with this standard are subject to equipment certification and operating requirements established by regional and national regulatory administrations. The PMD specification establishes minimum technical requirements for interoperability, based upon established regulations at the time this standard was issued. These regulations are subject to revision, or may be superseded. Requirements that are subject to local geographic regulations are annotated within the PMD specification. Regulatory requirements that do not affect interoperability are not addressed in this standard. Implementers are referred to the regulatory sources in Annex D for further information. Operation in countries within defined regulatory domains may be subject to additional or alternative national regulations.

18.3.8.4 Operating channel frequencies

18.3.8.4.1 Operating frequency range

The OFDM PHY shall not operate in frequency bands not allocated by a regulatory body in its operational region. Regulatory requirements for a given frequency band are set by the regulatory authority responsible for spectrum management in a given geographic region or domain. The particular channelization to be used for this standard is dependent on such allocation, as well as the associated regulations for use of the allocations. These regulations are subject to revision, or may be superseded.

In some regulatory domains, several frequency bands may be available for OFDM PHY-based WLANs. These bands may be contiguous or not, and different regulatory limits may be applicable. A compliant OFDM PHY shall support at least one frequency band in at least one regulatory domain. The support of specific regulatory domains, and bands within the domains, shall be indicated by PLME attributes dot11RegDomainsImplementedValue and dot11FrequencyBandsImplemented.

The OFDM PHY shall use dot11CurrentFrequency to determine the operating frequency.

18.3.8.4.2 Channel numbering

Channel center frequencies are defined at every integral multiple of 5 MHz above Channel starting frequency. The relationship between center frequency and channel number is given by Equation (18-27):

\[
\text{Channel center frequency} = \text{Channel starting frequency} + 5 \times n_{\text{ch}} \text{ (MHz)}
\] (18-27)

where

\[ n_{\text{ch}} = 1,\ldots,200. \]

Channel starting frequency is defined as dot11ChannelStartingFactor × 500 kHz or is defined as 5 GHz for systems where dot11OperatingClassesRequired is false or not defined.

For example, dot11ChannelStartingFactor = 10000 indicates that Channel 0 center frequency is 5.000 GHz. A channel center frequency of 5.000 GHz shall be indicated by dot11ChannelStartingFactor = 8000 and \( n_{\text{ch}} = 200 \). An SME managing multiple channel sets can change the channel set being managed by changing the value of dot11ChannelStartingFactor.

This definition provides a unique numbering system for all channels with 5 MHz between center frequencies, as well as the flexibility to define channelization sets for all current and future regulatory domains.
18.3.8.4.3 Channelization

The set of valid operating channel numbers by regulatory domain is defined in Annex E. As shown in Figure 18-11, no subcarrier is allocated on the channel center frequency.

18.3.8.5 Transmit and receive in-band and out-of-band spurious emissions

The OFDM PHY shall conform to in-band and out-of-band spurious emissions as set by regulatory bodies.

18.3.8.6 TX RF delay

The TX RF delay time shall be defined as the time between the issuance of a PMD.DATA.request primitive to the PMD and the start of the corresponding symbol at the air interface.

18.3.8.7 Slot time

The slot time for the OFDM PHY shall be 9 µs for 20 MHz channel spacing, shall be 13 µs for 10 MHz channel spacing, and shall be 21 µs for 5 MHz channel spacing.

Where dot11OperatingClassesRequired is true, the value of the slot time shall be increased by the value of 3 µs × coverage class. The default value of coverage class shall be 0.

NOTE—Distributed coordination function (DCF) operation over larger BSS diameters is facilitated by relaxing some PHY timing parameters, while maintaining compatibility with existing implementations in small BSS diameters.

18.3.8.8 Transmit and receive antenna port impedance

The transmit and receive antenna port(s) impedance shall be 50 Ω if the port is exposed.

18.3.9 PMD transmit specifications

18.3.9.1 General

The transmit specifications associated with the PMD sublayer are described in 18.3.9.2 to 18.3.9.8. In general, these are specified by primitives from the PLCP, and the transmit PMD entity provides the actual means by which the signals required by the PLCP primitives are imposed onto the medium.

18.3.9.2 Transmit power levels

The maximum allowable output power is measured in accordance with practices specified by the appropriate regulatory bodies.

18.3.9.3 Transmit spectrum mask

The transmit spectrum mask by regulatory domain is defined in Annex D and Annex E.

NOTE—In the presence of additional regulatory restrictions, the device needs to meet both the regulatory requirements and the mask defined here, i.e., its emissions need to be no higher at any frequency offset than the minimum of the values specified in the regulatory and default masks.

For operation using 20 MHz channel spacing, the transmitted spectrum shall have a 0 dBr (dB relative to the maximum spectral density of the signal) bandwidth not exceeding 18 MHz, –20 dBr at 11 MHz frequency offset, –28 dBr at 20 MHz frequency offset, and the maximum of –40 dBr and –53 dBm/MHz at 30 MHz frequency offset and above. The transmitted spectral density of the transmitted signal shall fall within the spectral mask, as shown in Figure 18-13. The measurements shall be made using a 100 kHz resolution
bandwidth and a 30 kHz video bandwidth.

**Figure 18-13—Transmit spectrum mask for 20 MHz transmission**

For operation using 10 MHz channel spacing, the transmitted spectrum shall have a 0 dBr bandwidth not exceeding 9 MHz, –20 dBr at 5.5 MHz frequency offset, –28 dBr at 10 MHz frequency offset, and the maximum of –40 dBr and –50 dBm/MHz at 15 MHz frequency offset and above. The transmitted spectral density of the transmitted signal shall fall within the spectral mask, as shown in Figure 18-14. The measurements shall be made using a 100 kHz resolution bandwidth and a 30 kHz video bandwidth.

**Figure 18-14—Transmit spectrum mask for 10 MHz transmission**

For operation using 5 MHz channel spacing, the transmitted spectrum shall have a 0 dBr bandwidth not exceeding 4.5 MHz, –20 dBr at 2.75 MHz frequency offset, –28 dBr at 5 MHz frequency offset, and the maximum of –40 dBr and –47 dBm/MHz at 7.5 MHz frequency offset and above. The transmitted spectral density of the transmitted signal shall fall within the spectral mask, as shown in Figure 18-15. The measurements shall be made using a 100 kHz resolution bandwidth and a 30 kHz video bandwidth.

**18.3.9.4 Transmission spurious**

Spurious transmissions from compliant devices shall conform to national regulations.
18.3.9.5 Transmit center frequency tolerance

The transmitted center frequency tolerance shall be ±20 ppm maximum for 20 MHz and 10 MHz channels and shall be ±10 ppm maximum for 5 MHz channels. The transmit center frequency and the symbol clock frequency shall be derived from the same reference oscillator.

18.3.9.6 Symbol clock frequency tolerance

The symbol clock frequency tolerance shall be ±20 ppm maximum for 20 MHz and 10 MHz channels, and shall be ±10 ppm maximum for 5 MHz channels. The transmit center frequency and the symbol clock frequency shall be derived from the same reference oscillator.

18.3.9.7 Modulation accuracy

18.3.9.7.1 Introduction

Transmit modulation accuracy specifications are described in 18.3.9.7. The test method is described in 18.3.9.8.

18.3.9.7.2 Transmitter center frequency leakage

Certain transmitter implementations may cause leakage of the center frequency component. Such leakage (which manifests itself in a receiver as energy in the center frequency component) shall not exceed −15 dB relative to overall transmitted power or, equivalently, +2 dB relative to the average energy of the rest of the subcarriers. The data for this test shall be derived from the channel estimation phase.

18.3.9.7.3 Transmitter spectral flatness

The average energy of the constellations in each of the spectral lines −16.. −1 and +1.. +16 shall deviate no more than ±4 dB from their average energy. The average energy of the constellations in each of the spectral lines −26.. −17 and +17.. +26 shall deviate no more than +4/−6 dB from the average energy of spectral lines −16.. −1 and +1.. +16. The data for this test shall be derived from the channel estimation step.
18.3.9.7.4 Transmitter constellation error

The relative constellation RMS error, averaged over subcarriers, OFDM frames, and packets, shall not exceed a data-rate dependent value according to Table 18-13.

Table 18-13—Allowed relative constellation error versus data rate

18.3.9.8 Transmit modulation accuracy test

The transmit modulation accuracy test shall be performed by instrumentation capable of converting the transmitted signal into a stream of complex samples at 20 Msample/s or more, with sufficient accuracy in terms of I/Q arm amplitude and phase balance, dc offsets, phase noise, etc. A possible embodiment of such a setup is converting the signal to a low IF with a microwave synthesizer, sampling the signal with a digital oscilloscope and decomposing it digitally into quadrature components.

The sampled signal shall be processed in a manner similar to an actual receiver, according to the following steps, or an equivalent procedure:

a) Start of frame shall be detected.

b) Transition from short sequences to channel estimation sequences shall be detected, and fine timing (with one sample resolution) shall be established.

c) Coarse and fine frequency offsets shall be estimated.

d) The packet shall be derotated according to estimated frequency offset.

e) The complex channel response coefficients shall be estimated for each of the subcarriers.

f) For each of the data OFDM symbols: transform the symbol into subcarrier received values, estimate the phase from the pilot subcarriers, derotate the subcarrier values according to estimated phase, and divide each subcarrier value with a complex estimated channel response coefficient.

g) For each data-carrying subcarrier, find the closest constellation point and compute the Euclidean distance from it.

h) Compute the RMS average of all errors in a packet. It is given by
where

\[ L_P \] is the length of the packet;

\[ N_f \] is the number of frames for the measurement;

\((I_0(i,j,k), Q_0(i,j,k))\) denotes the ideal symbol point of the \(i^{th}\) frame, \(j^{th}\) OFDM symbol of the frame, \(k^{th}\) subcarrier of the OFDM symbol in the complex plane;

\((I(i,j,k), Q(i,j,k))\) denotes the observed point of the \(i^{th}\) frame, \(j^{th}\) OFDM symbol of the frame, \(k^{th}\) subcarrier of the OFDM symbol in the complex plane (see Figure 18-16);

\[ P_0 \] is the average power of the constellation.

The vector error on a phase plane is shown in Figure 18-16.

The test shall be performed over at least 20 frames \((N_f)\), and the RMS average shall be taken. The packets under test shall be at least 16 OFDM symbols long. Random data shall be used for the symbols.

\[
Error_{RMS} = \frac{\sum_{i=1}^{N_f} \left\{ (I(i,j,k) - I_0(i,j,k))^2 + (Q(i,j,k) - Q_0(i,j,k))^2 \right\}}{N_f \times 52L_P \times P_0}
\]

(18-28)

\[ \text{Figure 18-16—Constellation error} \]

### 18.3.9.9 Time of Departure accuracy

The Time of Departure accuracy test evaluates \(\text{TIme\_OF\_DEPARTURE}\) against \(\text{aTxPmdTxStartRMS}\) and \(\text{aTxPmdTxStartRMS}\) against \(\text{TIme\_OF\_DEPARTURE\_ACCURACY\_TEST\_THRESH}\) as defined Annex T with the following test parameters:

- \(\text{MULTICOMPANY\_SAMPLING\_RATE}\) is \(20 \times 10^6 \left(1 + \left\lceil \frac{f_H - f_L}{20 \text{ MHz}} \right\rceil \right)\) sample/s

where

\[ f_H \]

is the nominal center frequency in Hz of the highest channel in the channel set

\[ f_L \]

is the nominal center frequency in Hz of the lowest channel in the channel set, the channel set is the set of channels upon which frames providing measurements are transmitted, the channel set comprises channels uniformly spaced across \(f_H - f_L \geq 50 \text{ MHz}\)
equals the smallest integer equal to or larger than \( x \)

— **FIRST_TRANSITION_FIELD** is the Short symbols.
— **SECOND_TRANSITION_FIELD** is the Long symbols.
— **TRAINING_FIELD** is the Long symbols windowed in a manner which should approximate the windowing described in 18.3.2.5 with \( T_{TR} = 100 \text{ ns} \) for 20 MHz channel spacing, \( T_{TR} = 200 \text{ ns} \) for 10 MHz channel spacing and \( T_{TR} = 400 \text{ ns} \) for 5 MHz channel spacing.
— **TIME_OF_DEPARTURE_ACCURACY_TEST_THRESH** is 80 ns.

NOTE—The indicated windowing applies to the time of departure accuracy test equipment, and not the transmitter or receiver.

### 18.3.10 PMD receiver specifications

#### 18.3.10.1 Introduction

The receive specifications associated with the PMD sublayer are described in 18.3.10.2 to 18.3.10.6.

#### 18.3.10.2 Receiver minimum input sensitivity

The packet error ratio (PER) shall be 10% or less when the PSDU length is 1000 octets and the rate-dependent input level is as shown in Table 18-14. The minimum input levels are measured at the antenna connector (noise factor of 10 dB and 5 dB implementation margins are assumed).

18.3.10.3 Adjacent channel rejection

The adjacent channel rejection shall be measured by setting the desired signal’s strength 3 dB above the rate-dependent sensitivity specified in Table 18-14 and raising the power of the interfering signal until 10% PER is caused for a PSDU length of 1000 octets. The power difference between the interfering and the desired channel is the corresponding adjacent channel rejection. The interfering signal in the adjacent channel shall be a conformant OFDM signal, unsynchronized with the signal in the channel under test. For a conformant OFDM PHY the corresponding rejection shall be no less than specified in Table 18-14.

An optional enhanced performance specification is provided for systems requiring improved immunity to out-of-channel interfering emissions. If a STA has dot11ACRType equal to 2, the adjacent channel rejection shall be no less than specified in Table 18-15. The interfering signal in the adjacent channel shall be a conformant OFDM signal, using transmit mask M (see D.2.4), unsynchronized with the signal in the channel under test. The corresponding minimum receiver sensitivities for each modulation and coding rate are the same as in Table 18-14.

NOTE—Transmit mask M is equivalent to class C (see D.2.2).

18.3.10.4 Nonadjacent channel rejection

The nonadjacent channel rejection shall be measured by setting the desired signal’s strength 3 dB above the rate-dependent sensitivity specified in Table 18-14, and raising the power of the interfering signal until a 10% PER occurs for a PSDU length of 1000 octets. The power difference between the interfering and the desired channel is the corresponding nonadjacent channel rejection. The interfering signal in the nonadjacent channel shall be a conformant OFDM signal, unsynchronized with the signal in the channel under test. For a conformed OFDM PHY, the corresponding rejection shall be no less than specified in Table 18-14.

An optional enhanced performance specification is provided for systems requiring improved immunity to out-of-channel interfering emissions. If a STA has dot11ACRType equal to 2, the nonadjacent channel rejection shall be no less than specified in Table 18-15. The interfering signal in the nonadjacent channel shall be a conformant OFDM signal, using transmit mask M (see D.2.4), unsynchronized with the signal in the channel under test. The corresponding minimum receiver sensitivities for each modulation and coding rate are the same as in Table 18-14.
18.3.10.5 Receiver maximum input level

The receiver shall provide a maximum PER of 10% at a PSDU length of 1000 octets, for a maximum input level of –30 dBm measured at the antenna for any baseband modulation.

18.3.10.6 CCA requirements

CCA shall detect a medium busy condition when the carrier sense/clear channel assessment (CS/CCA) mechanism detects a channel busy condition. For the operating classes requiring CCA-Energy Detect (CCA-ED), CCA shall also detect a medium busy condition when CCA-ED detects a channel busy condition.

The start of a valid OFDM transmission at a receive level equal to or greater than the minimum modulation and coding rate sensitivity (–82 dBm for 20 MHz channel spacing, –85 dBm for 10 MHz channel spacing, and –88 dBm for 5 MHz channel spacing) shall cause CS/CCA to indicate busy with a probability > 90% within 4 μs for 20 MHz channel spacing, 8 μs for 10 MHz channel spacing, and 16 μs for 5 MHz channel spacing. If the preamble portion was missed, the receiver shall hold the CCA signal busy for any signal 20 dB above the minimum modulation and coding rate sensitivity (–62 dBm for 20 MHz channel spacing, –65 dBm for 10 MHz channel spacing, and –68 dBm for 5 MHz channel spacing).

NOTE—CS/CCA detect time is based on finding the short sequences in the preamble, so when $T_{SYM}$ doubles, so does CS/CCA detect time.

For improved spectrum sharing, CCA-ED is required in some bands. The behavior class indicating CCA-ED is given in Table D-2. The operating classes requiring the corresponding CCA-ED behavior class are given in E.1. A STA that is operating within an operating class that requires CCA-ED shall operate with CCA-ED. The CCA-ED shall not be required for license-exempt operation in any band.

CCA-ED shall indicate a channel busy condition when the received signal strength exceeds the CCA-ED threshold as given by dot11OFDMEDThreshold. The CCA-ED thresholds for the operating classes requiring CCA-ED are subject to the criteria in D.2.5.

NOTE—The requirement to hold the CCA signal busy for any signal 20 dB above the minimum modulation and coding rate sensitivity (–62 dBm for 20 MHz channel spacing, –65 dBm for 10 MHz channel spacing, and –68 dBm for 5 MHz channel spacing) is a mandatory energy detect requirement on all Clause 18 receivers. Support for CCA-ED is an additional requirement that relates specifically to the sensitivities described in D.2.5.

18.3.10.7 Received Channel Power Indicator Measurement

The RCPI indicator is a measure of the received RF power in the selected channel for a received frame. This parameter shall be a measure by the PHY sublayer of the received RF power in the channel measured over the entire received frame or by other equivalent means that meet the specified accuracy. RCPI shall be a monotonically increasing, logarithmic function of the received power level defined in dBm. The allowed values for the RCPI parameter shall be an 8-bit value in the range from 0 to 220, with indicated values rounded to the nearest 0.5 dB as follows:

0: \[ \text{Power} \leq \text{–110 dBm} \]
1: \[ \text{Power} = \text{–109.5 dBm} \]
2: \[ \text{Power} = \text{–109.0 dBm} \]

and so on where

\[ \text{RCPI} = \left\lfloor \left( \text{Power in dBm} + 110 \right) \times 2 \right\rfloor \text{ for } 0 \text{ dBm} > \text{Power} > \text{–110 dBm} \]
220: Power ≥ –0 dBm

221–254: Reserved

255: Measurement not available

RCPI shall equal the received RF power within an accuracy of ±5 dB (95% confidence interval) within the specified dynamic range of the receiver. The received RF power shall be determined assuming a receiver noise equivalent bandwidth equal to the channel bandwidth multiplied by 1.1.

18.3.11 Transmit PLCP

The transmit PLCP is shown in Figure 18-17. In order to transmit data, the PHY-TXSTART.request primitive shall be enabled so that the PHY entity shall be in the transmit state. Further, the PHY shall be set to operate at the appropriate frequency through STA management via the PLME. Other transmit parameters, such as DATARATE and TX power, are set via the PHY-SAP with the PHY-TXSTART.request(TXVECTOR) primitive, as described in 18.2.2.
A clear channel shall be indicated by a PHY-CCA.indication(IDLE) primitive. The MAC considers this indication before issuing the PHY-TXSTART.request primitive. Transmission of the PPDU shall be initiated after receiving the PHY-TXSTART.request(TXVECTOR) primitive. The TXVECTOR elements for the PHY-TXSTART.request primitive are the PLCP header parameters DATARATE, SERVICE, and LENGTH and the PMD parameters TXPWR_LEVEL and TIME_OF_DEPARTURE_REQUESTED.

The PLCP shall issue PMD_TXPWRLVL and PMD_RATE primitives to configure the PHY. The PLCP shall then issue a PMD_TXSTART.request primitive, and transmission of the PLCP preamble and PLCP header, based on the parameters passed in the PHY-TXSTART.request primitive, shall be immediately initiated. If dot11MgmtOptionTODImplemented and dot11MgmtOptionTODActivated are true or if dot11MgmtOptionTimingMsmtActivated is true and the TXVECTOR parameter TIME_OF_DEPARTURE_REQUESTED is true, then the PLCP shall issue a PHY_TXSTART.confirm(TXSTATUS) primitive to the MAC, forwarding the TIME_OF_DEPARTURE corresponding to the time when the first frame energy is sent by the transmitting port and the TIME_OF_DEPARTURE_ClockRate parameter within the TXSTATUS vector. If dot11MgmtOptionTimingMsmtActivated is true, then the PLCP shall forward the value of TX_START_OF_FRAME_OFFSET in the TXSTATUS vector. Once PLCP preamble transmission is started, the PHY entity shall immediately initiate PLCP header encoding then data scrambling and data encoding, where the data shall be exchanged between the MAC and the PHY through a series of PHY-DATA.request(DATA) primitives issued by the MAC, and PHY-DATA.confirm primitives issued by the PHY. The modulation rate change, if any, shall be initiated from the SERVICE field data of the PLCP header, as described in 18.3.2.

The PHY proceeds with PSDU transmission through a series of data octet transfers from the MAC. The PLCP header parameter, SERVICE, and PSDU are encoded by the convolutional encoder with the bit-stealing function described in 18.3.5.6. At the PMD layer, the data octets are sent in bit 0–7 order and presented to the PHY through PMD_DATA.request primitives. Transmission can be prematurely terminated by the MAC through the PHY-TXEND.request primitive. PHY-TXSTART shall be disabled by the issuance of the PHY-TXEND.request primitive. Normal termination occurs after the transmission of the final bit of the last PSDU octet, according to the number supplied in the OFDM PHY preamble LENGTH field.

The packet transmission shall be completed and the PHY entity shall enter the receive state (i.e., PHY-TXSTART shall be disabled). Each PHY-TXEND.request primitive is acknowledged with a PHY-TXEND.confirm primitive from the PHY. If the coded PSDU (C-PSDU) length is not a multiple of the OFDM symbol length $N_{CBPS}$, the PSDU is padded prior to scrambling and coding (see 18.3.5.4).

In the PMD, the GI shall be inserted in every OFDM symbol as a countermeasure against severe delay spread.

A typical state machine implementation of the transmit PLCP is provided in Figure 18-18. Requests (.request) and confirmations (.confirm) are issued once with designated states.
At any stage in the above flow diagram, if a PHY_TXEND.request primitive is received.

**Figure 18-18—PLCP transmit state machine**
18.3.12 Receive PLCP

The receive PLCP is shown in Figure 18-19. In order to receive data, the PHY-TXSTART.request primitive shall be disabled so that the PHY entity is in the receive state. Further, through STA management (via the PLME) the PHY is set to the appropriate frequency. Other receive parameters, such as RSSI, RCPI, and indicated DATARATE, may be accessed via the PHY-SAP.

Upon receiving the transmitted PLCP preamble, a PMD_RSSI.indication primitive shall report a significant received signal strength level to the PLCP. This indicates activity to the MAC via PHY_CCA.indication primitive. A PHY_CCA.indication(BUSY) primitive shall be issued for reception of a signal prior to correct reception of the PLCP frame. The PMD primitive PMD_RSSI is issued to update the RSSI and parameter reported to the MAC.

After a PHY-CWA.indication primitive is issued, the PHY entity shall begin receiving the training symbols and searching for the SIGNAL in order to set the length of the data stream, the demodulation type, and the decoding rate. Once the SIGNAL is detected, without any errors detected by a single parity (even), FEC decode shall be initiated and the PLCP IEEE 802.11 SERVICE fields and data shall be received, decoded (a Viterbi decoder is recommended), and checked by ITU-T CRC-32. If the FCS by the ITU-T CRC-32 check...
fails, the PHY receiver shall return to the RX IDLE state, as depicted in Figure 18-19. Should the status of CCA return to the IDLE state during reception prior to completion of the full PLCP processing, the PHY receiver shall return to the RX IDLE state.

If the PLCP header reception is successful (and the SIGNAL field is completely recognizable and supported), a PHY-RXSTART.indication(RXVECTOR) primitive shall be issued. If dot11MgmtOptionTimingMsmtActivated is true, the PLCP shall do the following:

- Complete receiving the PLCP header and verify the validity of the PLCP Header.
- If the PLCP header reception is successful (and the SIGNAL field is completely recognizable and supported), a PHY-RXSTART.indication(RXVECTOR) primitive shall be issued and RX_START_OF_FRAME_OFFSET parameter within the RXVECTOR shall be forwarded (see 18.2.3).

NOTE—The RX_START_OF_FRAME_OFFSET value is used as described in 6.3.57 in order to estimate when the start of the preamble for the incoming frame was detected on the medium at the receive antenna port.

The RXVECTOR associated with this primitive includes the SIGNAL field, the SERVICE field, the PSDU length in octets, and the RSSI. Also, in this case, the OFDM PHY shall ensure that the CCA indicates a busy medium for the intended duration of the transmitted frame, as indicated by the LENGTH field.

The received PSDU bits are assembled into octets, decoded, and presented to the MAC using a series of PHY-DATA.indication(DATA) primitive exchanges. The rate change indicated in the IEEE 802.11 SIGNAL field shall be initiated from the SERVICE field data of the PLCP header, as described in 18.3.2. The PHY shall proceed with PSDU reception. After the reception of the final bit of the last PSDU octet indicated by the PLCP preamble LENGTH field, the receiver shall be returned to the RX IDLE state, as shown in Figure 18-19. A PHY-RXEND.indication(NoError) primitive shall be issued.

In the event that a change in the RSSI causes the status of the CCA to return to the IDLE state before the complete reception of the PSDU, as indicated by the PLCP LENGTH field, the error condition shall be reported to the MAC using a PHY-RXEND.indication(CarrierLost) primitive. The OFDM PHY shall ensure that the CCA indicates a busy medium for the intended duration of the transmitted packet.

If the indicated rate in the SIGNAL field is not receivable, a PHY-RXSTART.indication primitive shall not be issued. The PHY shall indicate the error condition using a PHY-RXEND.indication(UnsupportedRate) primitive and hold CCA busy for the calculated duration of the PPDU. If the PLCP header is receivable, but the parity check of the PLCP header is not valid, a PHY-RXSTART.indication primitive shall not be issued. The PHY shall indicate the error condition using a PHY-RXEND.indication(FormatViolation) primitive.

Any data received after the indicated data length are considered pad bits (to fill out an OFDM symbol) and should be discarded.

A typical state machine implementation of the receive PLCP is given in Figure 18-20.

18.4 OFDM PLME

18.4.1 PLME_SAP sublayer management primitives

Table 18-16 lists the MIB attributes that may be accessed by the PHY entities and the intralayer of higher level LMEs. These attributes are accessed via the PLME-GET, PLME-SET, PLME-RESET, and PLME-CHARACTERISTICS primitives defined in 6.5.
18.4.2 OFDM PHY MIB

All OFDM PHY MIB attributes are defined in Annex C, with specific values defined in Table 18-16. The column titled “Operational semantics” in Table 18-16 contains two types: static and dynamic. Static MIB attributes are fixed and cannot be modified for a given PHY implementation. Dynamic MIB attributes can be modified by some management entity.

18.4.3 OFDM TXTIME calculation

The value of the TXTIME parameter returned by the PLME-TXTIME.confirm primitive shall be calculated according to the following equation:

\[
\text{TXTIME} = T_{\text{PREAMBLE}} + T_{\text{SIGNAL}} + T_{\text{SYM}} \times N_{\text{SYM}}
\]  

where

- \( T_{\text{PREAMBLE}} \) is defined in Table 18-5
- \( T_{\text{SIGNAL}} \) is defined in Table 18-5
- \( T_{\text{SYM}} \) is defined in Table 18-5
- \( N_{\text{SYM}} \) is given by Equation (18-11).

18.4.4 OFDM PHY characteristics

The static OFDM PHY characteristics, provided through the PLME-CHARACTERISTICS service primitive, are shown in Table 18-17. The definitions for these characteristics are given in 6.5.

18.5 OFDM PMD sublayer

18.5.1 Scope and field of application

Subclause 18.5 describes the PMD services provided to the PLCP for the OFDM PHY. Also defined in 18.5 are the functional, electrical, and RF characteristics required for interoperability of implementations conforming to this specification. The relationship of this specification to the entire OFDM PHY is shown in Figure 18-21.

![PMD layer reference model]

18.5.2 Overview of service

The OFDM PMD sublayer accepts PLCP sublayer service primitives and provides the actual means by which data are transmitted or received from the medium. The combined function of the OFDM PMD sublayer primitives and parameters for the receive function results in a data stream, timing information, and associated receive signal parameters being delivered to the PLCP sublayer. A similar functionality shall be provided for data transmission.

18.5.3 Overview of interactions

The primitives associated with the IEEE 802.11 PLCP sublayer to the OFDM PMD fall into two basic categories:

a) Service primitives that support PLCP peer-to-peer interactions;

b) Service primitives that have local significance and support sublayer-to-sublayer interactions.

18.5.4 Basic service and options

18.5.4.1 General

All of the service primitives described in 18.5.4 are considered mandatory, unless otherwise specified.

18.5.4.2 PMD_SAP peer-to-peer service primitives

Table 18-18 indicates the primitives for peer-to-peer interactions.

18.5.5 PMD_SAP detailed service specification

18.5.5.1 Introduction

Subclause 18.5.5 describes the services provided by each PMD primitive.

18.5.5.2 PMD_DATA.request

18.5.5.2.1 Function

This primitive defines the transfer of data from the PLCP sublayer to the PMD entity.

18.5.5.2.2 Semantics of the service primitive

This primitive shall provide the following parameter:

```c
PMD_DATA.request(
    TXD_UNIT
)
```

The TXD_UNIT parameter shall be the n-bit combination of 0 and 1 for one symbol of OFDM modulation. If the length of a coded MPDU (C-MPDU) is shorter than n bits, 0 bits are added to form an OFDM symbol. This parameter represents a single block of data which, in turn, shall be used by the PHY to be encoded into an OFDM transmitted symbol.

18.5.5.2.3 When generated

This primitive shall be generated by the PLCP sublayer to request transmission of one OFDM symbol. The data clock for this primitive shall be supplied by the PMD layer based on the OFDM symbol clock.

18.5.5.2.4 Effect of receipt

The PMD performs transmission of the data.

18.5.5.3 PMD_DATA.indication

18.5.5.3.1 Function

This primitive defines the transfer of data from the PMD entity to the PLCP sublayer.

<table>
<thead>

</tr>
</tbody>
</table>
18.5.5.3.2 Semantics of the service primitive

This primitive shall provide the following parameter:

\[
PMD\_DATA.indication(\text{RXD\_UNIT})
\]

The RXD\_UNIT parameter shall be 0 or 1, and shall represent either a signal field bit or a data field bit after the decoding of the convolutional code by the PMD entity.

18.5.5.3.3 When generated

This primitive, generated by the PMD entity, forwards received data to the PLCP sublayer. The data clock for this primitive shall be supplied by the PMD layer based on the OFDM symbol clock.

18.5.5.3.4 Effect of receipt

The PLCP sublayer interprets the bits that are recovered as part of the PLCP or passes the data to the MAC sublayer as part of the MPDU.

18.5.5.4 PMD\_TXSTART.request

18.5.5.4.1 Function

This primitive, generated by the PHY PLCP sublayer, initiates PPDU transmission by the PMD layer.

18.5.5.4.2 Semantics of the service primitive

The semantics of this primitive are as follows:

\[
PMD\_TXSTART.request
\]

18.5.5.4.3 When generated

This primitive shall be generated by the PLCP sublayer to initiate the PMD layer transmission of the PPDU. The PHY-TXSTART.request primitive shall be provided to the PLCP sublayer prior to issuing the PMD\_TXSTART command.

18.5.5.4.4 Effect of receipt

PMD\_TXSTART initiates transmission of a PPDU by the PMD sublayer.

18.5.5.5 PMD\_TXEND.request

18.5.5.5.1 Function

This primitive, generated by the PHY PLCP sublayer, ends PPDU transmission by the PMD layer.

18.5.5.5.2 Semantics of the service primitive

The semantics of this primitive are as follows:

\[
PMD\_TXEND.request
\]
18.5.5.5.3 When generated

This primitive shall be generated by the PLCP sublayer to terminate the PMD layer transmission of the PPDU.

18.5.5.5.4 Effect of receipt

PMD_TXEND terminates transmission of a PPDU by the PMD sublayer.

18.5.5.6 PMD_TXPWRLVL.request

18.5.5.6.1 Function

This primitive, generated by the PHY PLCP sublayer, selects the power level used by the PHY for transmission.

18.5.5.6.2 Semantics of the service primitive

This primitive shall provide the following parameter:

\[
\text{PMD\_TXPWRLVL}\text{.request}(\quad \text{TXPWR\_LEVEL})
\]

TXPWR\_LEVEL selects which of the transmit power levels should be used for the current packet transmission. The number of available power levels shall be determined by the MIB parameter aNumberSupportedPowerLevels. See 18.3.9.2 for further information on the OFDM PHY power level control capabilities.

18.5.5.6.3 When generated

This primitive shall be generated by the PLCP sublayer to select a specific transmit power. This primitive shall be applied prior to setting PMD\_TXSTART into the transmit state.

18.5.5.6.4 Effect of receipt

PMD\_TXPWRLVL immediately sets the transmit power level to that given by TXPWR\_LEVEL.

18.5.5.7 PMD\_RATE.request

18.5.5.7.1 Function

This primitive, generated by the PHY PLCP sublayer, selects the modulation rate that shall be used by the OFDM PHY for transmission.

18.5.5.7.2 Semantics of the service primitive

This primitive shall provide the following parameter:

\[
\text{PMD\_RATE}\text{.request}(\quad \text{RATE})
\]

RATE selects which of the OFDM PHY data rates shall be used for MPDU transmission. See 18.3.8.7 for further information on the OFDM PHY modulation rates. The OFDM PHY rate change capability is described in detail in 18.3.7.
18.5.5.7.3 When generated

This primitive shall be generated by the PLCP sublayer to change or set the current OFDM PHY modulation rate used for the MPDU portion of a PPDU.

18.5.5.7.4 Effect of receipt

The receipt of PMD_RATE selects the rate that shall be used for all subsequent MPDU transmissions. This rate shall be used for transmission only. The OFDM PHY shall still be capable of receiving all the required OFDM PHY modulation rates.

18.5.5.8 PMD_RSSI.indication

18.5.5.8.1 Function

This primitive, generated by the PMD sublayer, provides the receive signal strength to the PLCP and MAC entity.

18.5.5.8.2 Semantics of the service primitive

This primitive shall provide the following parameter:

\[
\text{PMD\_RSSI\_indication}(\text{RSSI})
\]

The RSSI shall be a measure of the RF energy received by the OFDM PHY. RSSIs of up to 8 bits (256 levels) are supported.

18.5.5.8.3 When generated

This primitive shall be generated by the PMD when the OFDM PHY is in the receive state. It shall be available continuously to the PLCP which, in turn, shall provide the parameter to the MAC entity.

18.5.5.8.4 Effect of receipt

This parameter shall be provided to the PLCP layer for information only. The RSSI may be used as part of a CCA scheme.

18.5.5.9 PMD_RCPI.indication

18.5.5.9.1 Function

This primitive, generated by the PMD sublayer, provides the RCPI to the PLCP and MAC entity.

18.5.5.9.2 Semantics of the service primitive

The primitive shall provide the following parameter:

\[
\text{PMD\_RCPI\_indication}(\text{RCPI})
\]

The RCPI shall be a measure of the channel power received by the OFDM PHY. RCPI indications of 8 bits are supported, as defined in 18.3.10.7.
18.5.5.9.3 When generated

This primitive shall be generated by the PMD when the OFDM PHY is in the receive state. It shall be continuously available to the PLCP, which in turn provides the parameter to the MAC entity.

18.5.5.9.4 Effect of receipt

This parameter shall be provided to the PLCP layer for information only. The RCPI may be used in conjunction with RSSI to measure input signal quality.
19. Extended Rate PHY (ERP) specification

19.1 Overview

19.1.1 General

This clause specifies further rate extension of the PHY for the DSSS system of Clause 16 and the extensions of Clause 17. Hereinafter the PHY defined in this clause is known as the ERP. This PHY operates in the 2.4 GHz ISM band.

19.1.2 Introduction

The ERP builds on the payload data rates of 1 and 2 Mb/s, as described in Clause 16, that use DSSS modulation and builds on the payload data rates of 1, 2, 5.5, and 11 Mb/s, as described in Clause 17, that use DSSS, CCK, and optional PBCC modulations. The ERP draws from Clause 18 to provide additional payload data rates of 6, 9, 12, 18, 24, 36, 48, and 54 Mb/s. Of these rates, transmission and reception capability for 1, 2, 5.5, 6, 11, 12, and 24 Mb/s data rates is mandatory.

Two additional optional ERP-PBCC modulation modes with payload data rates of 22 and 33 Mb/s are defined. An ERP-PBCC STA may implement 22 Mb/s alone or 22 and 33 Mb/s. An optional modulation mode known as DSSS-OFDM is also incorporated with payload data rates of 6, 9, 12, 18, 24, 36, 48, and 54 Mb/s.

The ERP-PBCC option is obsolete. Consequently, this option may be removed in a later revision of the standard.

The use of the DSSS-OFDM option is deprecated, and this option may be removed in a later revision of the standard.

19.1.3 Operational modes

The radio portion of all Clause 19-compliant ERP systems implements all mandatory modes of Clause 18 and Clause 17, except it uses the 2.4 GHz frequency band and channelization plan specified in 17.4.6. The ERP has the capability to decode all Clause 16 and Clause 17 PLCPs and all ERP-OFDM PLCPs. In addition, it is mandatory that all ERP-compliant equipment be capable of sending and receiving the short preamble that is (and remains) optional for Clause 17 PHYs.

The ERP has the capability to detect ERP and Clause 17 preambles whenever a CCA is requested. Because protection mechanisms are not required in all cases, the ERP CCA mechanisms for all preamble types shall be active at all times.

An ERP BSS is capable of operating in any combination of available ERP modes (Clause 19 PHYs) and NonERP modes (Clause 16 or Clause 17 PHYs). For example, a BSS could operate in an ERP-OFDM-only mode, a mixed mode of ERP-OFDM and ERP-DSSS/CCK, or a mixed mode of ERP-DSSS/CCK and NonERP. When options are enabled, combinations are also allowed.

The changes to other parts of this standard required to implement the ERP are summarized as follows:

a) ERP-DSSS/CCK

   1) The PHY uses the capabilities of Clause 17 with the following exceptions:

      i) Support of the short PLCP PPDU header format capability of 17.2.2.3 is mandatory.
      ii) CCA (see 17.4.8.5) has a mechanism that detects all mandatory Clause 19 sync symbols.
      iii) The maximum input signal level (see 17.4.8.3) is –20 dBm.
iv) Locking the transmit center frequency and the symbol clock frequency to the same reference oscillator is mandatory.

b) ERP-OFDM
   1) The PHY uses the capabilities of Clause 18 with the following exceptions:
      i) The frequency plan is in accordance with 17.4.6.2 and 17.4.6.3 instead of 18.3.8.4.
      ii) CCA has a mechanism that detects all mandatory Clause 19 sync symbols.
      iii) The frequency accuracy (see 18.3.9.5 and 18.3.9.6) is ±25 PPM.
      iv) The maximum input signal level (see 18.3.10.5) is −20 dBm.
      v) The slot time is 20 µs in accordance with 17.3.3, except that an optional 9 µs slot time may be used when the BSS consists of only ERP STAs.
      vi) SIFS time is 10 µs in accordance with 17.3.3. See 19.3.2.4 for more detail.

c) ERP-PBCC (Optional)
   1) This is a single carrier modulation scheme that encodes the payload using a 256-state packet binary convolutional code. These are extensions to the PBCC modulation in Clause 17. ERP-PBCC modes with payload data rates of 22 Mb/s and 33 Mb/s are defined in 19.6.

d) DSSS-OFDM (Optional)
   1) This is a hybrid modulation combining a DSSS preamble and header with an OFDM payload transmission. DSSS-OFDM modes with payload data rates of 6, 9, 12, 18, 24, 36, 48, and 54 Mb/s are defined in 19.7.
   2) If the optional DSSS-OFDM mode is used, the supported rates in that mode are the same as the ERP-OFDM supported rates.

The 2.4 GHz ISM band is a shared medium, and coexistence with other devices such as Clause 16 and Clause 17 STAs is an important issue for maintaining high performance in Clause 19 (ERP) STAs. The ERP modulations (ERP-OFDM, ERP-PBCC, and DSSS-OFDM) have been designed to coexist with existing Clause 16 and Clause 17 STAs. This coexistence is achieved by several means, including virtual CS (RTS/CTS or CTS-to-self), CSMA/CA protocols, and MSDU fragmentation.

19.1.4 Scope

This clause specifies the ERP entity and the deviations from earlier clauses to accommodate it. It is organized by reference to the relevant earlier clauses to avoid excessive duplication.

The ERP consists of the following two protocol functions:

a) A physical layer convergence function that adapts the capabilities of the PMD system to the PHY service available. This function is supported by the PLCP, which defines a method for mapping the MPDUs into a framing format suitable for sending and receiving user data and management information between two or more STAs using the associated PMD system. The PHY exchanges PPDUs that contain PSDUs. The MAC uses the PHY service, so each MPDU corresponds to a PSDU that is carried in a PPDU.

b) A PMD system, whose function defines the characteristics and method of transmitting and receiving data through a WM between two or more STAs; each using the ERP.

19.1.5 ERP functions

The architecture of the ERP is depicted in the ISO/IEC basic reference model shown in Figure 17-10 of 17.4.1. The ERP contains three functional entities: the PMD function, the PLCP, and the layer management function.
The ERP service is provided to the MAC through the PHY service primitives described in Clause 7. Interoperability is addressed by use of the CS mechanism specified in 9.3.2.1 and the protection mechanism in 9.23. This mechanism allows NonERP STAs to know of ERP traffic that they cannot demodulate so that they may defer the medium to that traffic.

### 19.2 PHY-specific service parameter list

The architecture of the IEEE 802.11 MAC is intended to be PHY independent. Some PHY implementations require PHY-dependent MAC state machines running in the MAC sublayer in order to meet certain PMD requirements. The PHY-dependent MAC state machine resides in a sublayer defined as the MLME. In certain PMD implementations, the MLME may need to interact with the PLME as part of the normal PHY SAP primitives. These interactions are defined by the PLME parameter list currently defined in the PHY service primitives as TXVECTOR, TXSTATUS, and RXVECTOR. The list of these parameters and the values they may represent are defined in the specific PHY specifications for each PMD. This subclause addresses the TXVECTOR, TXSTATUS, and RXVECTOR for the ERP. The service parameters for TXVECTOR, TXSTATUS, and RXVECTOR shall follow 18.2.2, 18.2.4, and 18.2.3, respectively.

Several service primitives include a parameter vector. DATARATE and LENGTH are described in 7.3.4.5. The remaining parameters are considered to be management parameters and are specific to this PHY.

The parameters in Table 19-1 are defined as part of the TXVECTOR parameter list in the PHY-TXSTART.request and PLME_TXTIME.request primitives.

### Table 19-1—TXVECTOR parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>

19.3 Extended Rate PLCP sublayer

19.3.1 Introduction

Subclause 19.3 provides a PLCP for the ERP. The convergence procedure specifies how PSDUs are converted to and from PPDU at the transmitter and receiver. The PPDU is formed during data transmission by appending the PSDU to the Extended Rate PLCP preamble and header. At the receiver, the PLCP preamble and header are processed to aid in the demodulation and delivery of the PSDU.

19.3.2 PPDU format

19.3.2.1 General

An ERP STA shall support three different preamble and header formats. The first is the long preamble and header described in 19.3.2.2 (and based on 17.2.2.2 with redefinition of reserved bits defined therein). This PPDU provides interoperability with Clause 17 STAs when using the 1, 2, 5.5, and 11 Mb/s data rates; the optional DSSS-OFDM modulation at all OFDM rates; and the optional ERP-PBCC modulation at all ERP-PBCC rates. The second is the short preamble and header described in 19.3.2.3 (and based on 17.2.2.3 where it is optional). The short preamble supports the rates 2, 5.5, and 11 Mb/s as well as DSSS-OFDM and ERP-PBCC. The third is the ERP-OFDM preamble and header specified in 19.3.2.4 (and based on 18.3.2). The ERP has two optional PPDU formats, described in 19.3.2.5 and 19.3.2.7, to support the optional DSSS-OFDM modulation rates.
19.3.2.2 Long preamble PPDU format

19.3.2.2.1 General

Figure 17-1 of 17.2.2.2 shows the basic format for the long preamble PPDU. This preamble is appropriate for use with the 1, 2, 5.5, and 11 Mb/s (Clause 17) modes and is compatible with BSSs using these modes. To support the optional modes included in the ERP, the long preamble PPDU only differs from 17.2.2.2 in the following:

a) The use of one bit in the SERVICE field to indicate when the optional ERP-PBCC mode is being used.

b) The use of two additional bits in the SERVICE field to resolve the length ambiguity when the optional ERP-PBCC-22 and ERP-PBCC-33 modes are being used.

c) Three additional optional rates given by the following SIGNAL field octets where the LSB is transmitted first in time:
   1) X'DC' (MSB to LSB) for 22 Mb/s ERP-PBCC
   2) X'21' (MSB to LSB) for 33 Mb/s ERP-PBCC
   3) X'1E' (MSB to LSB) for all DSSS-OFDM rates

Three bits of the SERVICE field have been defined to support the optional modes of the ERP standard. Table 19-4 shows graphically the assignment of the bits within the SERVICE field. The bits b0, b1, and b4 are reserved and shall be set to 0. Bit b2 is used to indicate that the transmit frequency and symbol clocks are derived from the same oscillator. For all ERP systems, the Locked Clock Bit shall be set to 1, when transmitting at an ERP-PBCC rate or at a data rate described in Clause 17. Bit b3 is used to indicate if the data are modulated using the optional ERP-PBCC modulation. Bit b3 is defined in 17.2.3.5 with the caveat that the ERP-PBCC mode now has the additional optional rates of 22 Mb/s and 33 Mb/s as defined in 19.3.3.2. Bits b5, b6, and b7 are used to resolve data field length ambiguities for the optional ERP-PBCC-11 to ERP-PBCC-33 modes. These bits are fully defined in 19.6. Bit b7 is also used to resolve data field length ambiguities for the CCK 11 Mb/s mode and is defined in 17.2.3.6. Bits b3, b5, and b6 are set to 0 for CCK.

19.3.2.2.2 ERP PLCP length field calculation

For the long and short preamble modes other than PBCC, the length field shall be calculated as in 17.2.3.6.

19.3.2.2.3 ERP-PBCC PLCP length (LENGTH) field calculation

For the ERP-PBCC PLCP length field, the transmitted value shall be determined from the LENGTH and DataRate parameters in the TXVECTOR issued with the PMD-TXSTART.request primitive described in 17.4.5.7.

The length field provided in the TXVECTOR is in octets and is converted to microseconds for inclusion in the PLCP LENGTH field. The Length Extension bits are provided to resolve the ambiguity in the number of
octets that is described by an integer number of microseconds for any data rate over 8 Mb/s. These bits are used to indicate which of the smaller potential number of octets is correct.

- 11 Mb/s PBCC: see 17.2.3.6.
- 22 Mb/s ERP-PBCC: Length = (number of octets + 1) × 4/11, rounded up to the next integer; the SERVICE field bits b6 and b7 shall each indicate a 0 if the rounding took less than 4/11; the SERVICE field bit b6 shall indicate a 0, and b7 shall indicate a 1 if the rounding took 4/11 or more and less than 8/11; and the SERVICE field bit b6 shall indicate a 1, and b7 shall indicate a 0 if the rounding took 8/11 or more.
- 33 Mb/s ERP-PBCC: Length = (number of octets + 1) × 8/33, rounded up to the next integer; the SERVICE field bits b5, b6, and b7 shall each indicate a 0 if the rounding took less than 8/33; the SERVICE field bit b5 shall indicate a 0, b6 shall indicate a 0, and b7 shall indicate a 1 if the rounding took more than or equal to 8/33 and less than 16/33; the SERVICE field bit b5 shall indicate a 0, b6 shall indicate a 1, and b7 shall indicate a 0 if the rounding took more than or equal to 16/33 and less than 24/33; the SERVICE field bit b5 shall indicate a 1, b6 shall indicate a 1, and b7 shall indicate a 0 if the rounding took more than or equal to 24/33 and less than 32/33; the SERVICE field bit b5 shall indicate 1, b6 shall indicate a 0, and b7 shall indicate a 0 if the rounding took 32/33 or more.

At the receiver, the number of octets in the MPDU is calculated as follows:

- 22 Mb/s ERP-PBCC: Number of octets = (Length × 11/4) – 1, rounded down to the next integer, minus 1 if the SERVICE field bit b6 is a 0 and b7 is a 1, or minus 2 if the SERVICE field bit b6 is a 1 and b7 is a 0.
- 33 Mb/s ERP-PBCC: Number of octets = (Length × 33/8) – 1, rounded down to the next integer, minus 1 if the SERVICE field bit b5 is a 0, b6 is a 0, and b7 is a 1, or minus 2 if the SERVICE field bit b5 is a 0, b6 is a 1, or minus 3 if the SERVICE field bit b5 is a 0, b6 is a 1, and b7 is a 1, or minus 4 if the SERVICE field bit b5 is a 1, b6 is a 0, and b7 is a 0.

Table 19-5 shows an example calculation for several packet lengths of ERP-PBCC at 22 Mb/s.

19.3.2.3 Short preamble PPDU format

Figure 17-2 of 17.2.2.3 shows the basic format for the short preamble PPDU. For the ERP, support for this preamble is mandatory. The short preamble is appropriate for use with 2, 5.5, and 11 Mb/s modes. The bits of the Short PLCP SERVICE field and RATE field are the same as for the Long PLCP SERVICE field and RATE field and are defined in 19.3.2.2.

19.3.2.4 ERP-OFDM PPDU format

The format, preamble, and headers for the ERP-OFDM PLCP PPDU are described in 18.3.2 to 18.3.5. For the ERP-OFDM modes, the DATA field that contains the SERVICE field, the PSDU, the TAIL bits, and the PAD bits shall follow 18.3.5.

For ERP-OFDM modes, an ERP packet is followed by a period of no transmission with a length of 6 µs called the signal extension. The purpose of this extension is to make the TXTIME calculation in 19.8.3 result in a transmission duration interval that includes an additional 6 µs. The SIFS time for Clause 18 packets is 16 µs, and the SIFS time for Clause 17 packets is 10 µs. The longer SIFS time in Clause 18 is to allow extra time for the convolutional decode process to finish. As Clause 19 packets use a SIFS time of 10 µs, this extra 6 µs length extension is used to ensure that the transmitter computes the Duration field in the MAC header incorporating the 6 µs of “idle time” following each ERP-OFDM transmission. This ensures that the NAV value of Clause 17 STAs is set correctly.

The “CS mechanism” described in 9.3.2.1 combines the NAV state and the STA’s transmitter status with physical CS to determine the busy/idle state of the medium. The time interval between frames is called the IFS. A STA shall determine that the medium is idle through the use of the CCA mechanism for the interval specified. The starting reference of slot boundaries is the end of the last symbol of the previous frame on the medium. For ERP-OFDM frames, this includes the length extension. For ERP-OFDM frames, a STA shall generate the PHY RX_END indication, 6 µs after the end of the last symbol of the previous frame on the medium. This adjustment shall be performed by the STA based on local configuration information set using the PLME SAP.

19.3.2.5 DSSS-OFDM long preamble PPDU format

Both long and short preambles and headers as previously described in 19.3.2.2 and 19.3.2.3 are used with DSSS-OFDM.

For all DSSS-OFDM rates and preamble modes, the PLCP SIGNAL field described in 17.2.3.4 shall be set to a 3 Mb/s value. That is, the 8 bit value is set to ‘X’1E’ (MSB to LSB). For DSSS-OFDM, this value is simply a default setting used for BSS compatibility and to ensure that NonERP STAs read the length field and defer the medium for that time even though they cannot demodulate the MPDU due to unsupported rates.

Figure 19-1 shows the PPDU format for the long preamble case. As seen, the PSDU is appended to the PLCP preamble and the PLCP header. The PLCP preamble is the same as described in 17.2.3.2 and 17.2.3.3. The PLCP header is similar to the one described in 19.3.2.2. The PSDU has a format that is nearly identical to a Clause 18 PLCP. The differences are described in 19.3.3.4.

The scrambler of 17.2.4 is used to scramble the DSSS-OFDM PLCP header, and the scrambler in 18.3.5.5 is used to scramble the data symbols in the OFDM segment.
19.3.2.6 DSSS-OFDM PLCP length field calculation

For both the long and the short preamble PLCP cases, the length field calculation in terms of data packet length is as follows:

\[
\text{LENGTH} = \text{PSDUsyncOFDM} + \text{PSDUSignalOFDM} + \\
4 \times \text{Ceiling}((\text{PLCPServiceBits} + 8 \times (\text{NumberOfOctets}) + \text{PadBits}) / N_{DBPS}) + \text{SignalExtension}
\]

where
- \(\text{PSDUsyncOFDM}\) is 8 μs (OFDM long training symbols)
- \(\text{PSDUSignalOFDM}\) is 4 μs
- \(\text{Ceiling}\) is a function that returns the smallest integer value greater than or equal to its argument value
- \(\text{PLCPServiceBits}\) is 8 bits
- \(\text{NumberOfOctets}\) is the number of data octets in the PSDU
- \(\text{PadBits}\) is 6 bits
- \(N_{DBPS}\) is the number of data bits per OFDM symbol
- \(\text{SignalExtension}\) is 6 μs

The length field is defined in units of microseconds and shall correspond to the calculated length of the PSDU. Note that the length extension bits in the Signal field are not needed or used for DSSS-OFDM.
19.3.2.7 Short DSSS-OFDM PLCP PPDU format

The short PLCP preamble and header are used to maximize the throughput by reducing the overhead associated with the preamble and header. Figure 19-2 shows the short preamble PLCP PPDU format. As seen, the PSDU is appended to the PLCP preamble and the PLCP header. The short PLCP preamble is described in 17.2.3.9 and 17.2.3.10. The PLCP header is as described in 19.3.2.5. The PSDU has a format that is nearly identical to Clause 18 PLCP. The differences are described in 19.3.3.4.

![Figure 19-2—Short preamble PPDU format for DSSS-OFDM](image_url)

19.3.3 PLCP data modulation and rate change

19.3.3.1 Long and short preamble formats

The long and short PLCP preamble and the long PLCP header shall be transmitted using the 1 Mb/s DBPSK modulation. The short PLCP header shall be transmitted using the 2 Mb/s modulation. The SIGNAL and SERVICE fields combined shall indicate the modulation and rate that shall be used to transmit the PSDU. The transmitter and receiver shall initiate the modulation and rate indicated by the SIGNAL and SERVICE fields, starting with the first octet of the PSDU. The PSDU transmission rate shall be set by the DATARATE parameter in the TXVECTOR, issued with the PHY-TXSTART.request primitive described in 17.4.5.2.

Four modulation formats are mandatory, 1 Mb/s and 2 Mb/s ERP-DSSS and 5.5 Mb/s and 11 Mb/s ERP-CCK, and they are specified in 17.4.6.4.

Four optional ERP-PBCC modulation formats and data rates are specified for the ERP. They shall be based on PBCC 5.5, 11, 22, and 33 Mb/s modulations. The rates of 5.5 Mb/s and 11 Mb/s are described in 17.4.6.7. No change in the spectral mask of 17.4.7.4 is required for these modes.
19.3.3.2 ERP-PBCC 22 Mb/s and 33 Mb/s formats

In the PBCC encoder, incoming data are first encoded with a packet binary convolutional code. A cover code (as defined in PBCC modes in 17.4.6.7) is applied to the encoded data prior to transmission through the channel.

The packet binary convolutional code that is used is a 256-state, rate 2/3 code. The generator matrix for the code is given as

\[ G = \begin{bmatrix} 1 + D^4 & D & D + D^3 \\ D^3 & 1 + D^2 + D^4 & D + D^3 \end{bmatrix} \]  

(19-1)

In octal notation, the generator matrix is given by

\[ G = \begin{bmatrix} 21 & 2 & 12 \\ 10 & 25 & 12 \end{bmatrix} \]  

(19-2)

As the system is frame (PPDU) based, the encoder shall be in state zero; i.e., all memory elements contain 0, at the beginning of every PPDU. The encoder shall also be placed in a known state at the end of every PPDU to prevent the data bits near the end of the PPDU from being decoded incorrectly. This is achieved by appending 1 octet containing all zeros to the end of the PPDU prior to transmission and discarding the final octet of each received PPDU.

An encoder block diagram is shown in Figure 19-3. It consists of two paths of four memory elements each. For every pair of data bits input, three output bits are generated. The output of the convolutional code is mapped to an 8-PSK constellation; each 3-bit output sequence from the packet binary convolutional encoder is used to produce one symbol. This yields a throughput of two information bits per symbol. In ERP-PBCC-22 and ERP-PBCC-33, the input data stream is divided into pairs of adjacent bits. In each pair, the first bit is fed to the upper input of the convolutional encoder, and the second is fed to the lower input of the convolutional encoder. An illustration of the mapping for the \(j\)th \((j \geq 0)\) pair of input bits \((b_{2j}, b_{2j+1})\) is given in Figure 19-3.

![Figure 19-3—22/33 Mb/s ERP-PBCC convolutional encoder](image)
The phase of the first complex chip of the 22 Mb/s PSDU shall be defined with respect to the phase of the last chip of the PCLP header, i.e., the last chip of the CRC check. The phase of the first complex chip of the 33 Mb/s PSDU shall be defined with respect to the phase of the last chip of the clock switch section, i.e., the last chip of the ReSync field. The bits \((y_2 \ y_1 \ y_0) = (0, 0, 0)\) shall indicate the same phase as the last chip of the CRC check. The other seven combinations of \((y_2 \ y_1 \ y_0)\) shall be defined with respect to this reference phase as shown in Figure 19-4.

The mapping from BCC outputs to 8-PSK constellation points is determined by a pseudorandom cover sequence. The cover sequence is the same one as described in 17.4.6.7. The current binary value of this sequence at every given point in time is taken as shown in Figure 19-4. The mapping is shown in Figure 19-4.

ERP-PBCC mode achieves a 33 Mb/s data rate by using a 16.5 MHz clock for the data portion of the packet. The data portion is otherwise identical to the 22 Mb/s ERP-PBCC modulations. The structure and clock speed of the preamble is the same as in Clause 17. An extra clock switch section between the preamble and the data portion is added, with the format described below. The same pulse shape shall be used in each clock domain.

When the clock is switched from 11 MHz to 16.5 MHz, the clock switching structure in Figure 19-5 is used.
19.3.3.3 ERP-OFDM format

PLCP modulation and rate change for the ERP-OFDM frame format follows 18.3.7.

19.3.3.4 Long and short DSSS-OFDM PLCP format

19.3.3.4.1 General

The scrambler of 17.2.4 is used to scramble the DSSS-OFDM PLCP header, and the scrambler in 18.3.5.5 is used to scramble the data symbols in the OFDM segment.

19.3.3.4.2 Overview of the DSSS-OFDM PLCP PSDU encoding process

This subclause contains the definitions and procedure for forming the PSDU portion of the DSSS-OFDM PLCP. Figure 19-6 shows an expanded view of the DSSS-OFDM PSDU. The PSDU is composed of four major sections. The first is the long sync training sequence that is used for acquisition of receiver parameters by the OFDM demodulator. The long sync training sequence for DSSS-OFDM is identical to the long training symbols described in 18.3.3. The second section is the OFDM SIGNAL field that provides the demodulator information on the OFDM data rate and length of the OFDM data section. The SIGNAL field for DSSS-OFDM is identical to the SIGNAL field described in 18.3.4. After the SIGNAL field is the data section of the PSDU. This is identical to the modulation procedure described in 18.3.2.2 in Step c) to Step m). After the data section, the PSDU for DSSS-OFDM appends a signal extension section to provide additional processing time for the OFDM demodulator. This signal extension is a period of no transmission as described in 19.3.3.4.6.

![Figure 19-6—DSSS-OFDM PSDU](image)

19.3.3.4.3 Long sync training sequence definition

The long sync training sequence is defined in 18.3.3.

19.3.3.4.4 OFDM signal field definition

The DSSS-OFDM SIGNAL field is defined in 18.3.4. Note that the length conveyed by the SIGNAL field is calculated as described in 18.3.4. That is, the length conveyed by this field does not include the signal extension described in 19.3.3.4.6.
19.3.3.4.5 Data symbol definition

The same process as Step c) to Step m) of 18.3.2.2 is used to encode the data symbols’ portion of the DSSS-OFDM PSDU.

19.3.3.4.6 DSSS-OFDM signal extension

The DSSS-OFDM signal extension shall be a period of no transmission of 6 \( \mu s \) length. It is inserted to allow more time to finish the convolutional decoding of the OFDM segment waveform and still meet the 10 \( \mu s \) SIFS requirement of the ERP.

19.3.4 PLCP transmit procedure

The transmit procedure depends on the data rate and modulation format requested. For data rates of 1, 2, 5.5, 11, 22, and 33 Mb/s, the PLCP transmit procedure shall follow 17.2.5. For the ERP_OFDM rates of 6, 12, and 24 Mb/s and the rates of 9, 18, 36, 48, and 54 Mb/s, the PLCP transmit procedure shall follow 18.3.11.

The transmit procedures for the optional DSSS-OFDM mode using the long or short PLCP preamble and header are the same as those described in 17.2.5, and they do not change apart from the ability to transmit a higher rate PSDU using DSSS-OFDM.

19.3.5 CCA

The PLCP shall provide the capability to perform a CCA and report the results of the assessment to the MAC. The CCA mechanism shall detect a “medium busy” condition for all supported preamble and header types. That is, the CCA mechanism shall detect that the medium is busy for the PLCP PPDUs specified in 18.3.3 and 17.2.2. The CCA mechanism performance requirements are given in 19.4.7.

The ERP shall provide the capability to perform CCA according to the following method:

CCA Mode (ED and CS): A combination of CS and energy above threshold. CCA shall have a mechanism for CS that detects all mandatory Clause 19 sync symbols. This CCA’s mode’s CS shall include both Barker code sync detection and OFDM sync symbol detection. CCA shall report busy at least while a PPDU with energy above the ED threshold is being received at the antenna.

The ED status shall be given by the PMD primitive, PMD_ED. The CS status shall be given by PMD_CS. The status of PMD_ED and PMD_CS is used in the PLCP convergence procedure to indicate activity to the MAC through the PHY-CCA.indication primitive. A busy channel shall be indicated by PHY-CCA.indication primitive of class BUSY. A clear channel shall be indicated by PHY-CCA.indication primitive of class IDLE.

19.3.6 PLCP receive procedure

This subclause describes the procedure used by receivers of the ERP. An ERP receiver shall be capable of receiving 1, 2, 5.5, and 11 Mb/s PLCPs using either the long or short preamble formats described in Clause 17 and shall be capable of receiving 6, 12, and 24 Mb/s using the modulation and preamble described in Clause 18. The PHY may also implement the ERP-PBCC modulation at rates of 5.5, 11, 22, and 33 Mb/s; the ERP-OFDM modulations at rates of 9, 18, 36, 48, and 54 Mb/s; and/or the DSSS-OFDM modulation rates of 6, 9, 12, 18, 24, 36, 48, and 54 Mb/s. The receiver shall be capable of detecting the preamble type (ERP-OFDM, short preamble, or long preamble) and the modulation type. These values shall be reported in the RXVECTOR (see 19.2).

Upon the receipt of a PPDU, the receiver shall first distinguish between the ERP-OFDM preamble and the single carrier modulations (long or short preamble). In the case where the preamble is an ERP-OFDM preamble, the PLCP receive procedure shall follow the procedure described in 18.3.12. Otherwise, the
receiver shall then distinguish between the long preamble and short preamble as specified in 17.2.2. The receiver shall then demodulate the SERVICE field to determine the modulation type as specified in 19.3.2.2 or 19.3.2.3. For short preamble and long preamble using ERP-DSSS, ERP-CCK, or ERP-PBCC modulations, the receiver shall then follow the receive procedure described in 17.2.6.

A receiver that supports DSSS-OFDM is capable of receiving all rates specified in Clause 16 and all mandatory rates in Clause 18 and Clause 17. If the SIGNAL field indicates 3 Mb/s, the receiver shall attempt to receive a DSSS-OFDM packet. The remaining receive procedures for a DSSS-OFDM-capable receiver are the same as those described in 17.2.6, and they do not change apart from the ability to receive DSSS-OFDM in the PSDU. If DSSS-OFDM is being received, the receiver shall handle the modulation transition requirements as described in 19.7.3. The receiver shall then follow the receive procedure described in 18.3.12.

19.4 ERP PMD operating specifications (general)

19.4.1 Introduction

Subclauses 19.4.2 to 19.4.8 provide general specifications for the ERP PMD sublayers. These specifications are based on 18.3.8 except where noted.

19.4.2 Regulatory requirements

All systems shall comply with the appropriate regulatory requirements for operation in the 2.4 GHz band.

19.4.3 Operating channel frequencies

The ERP shall operate in the frequency ranges specified in 17.4.6.3, as allocated by regulatory bodies in the United States, Europe, and Japan. OFDM operation in channel 14 may not be allowed in Japan. The channel numbering and the number of operating channels shall follow Table 17-9 of 17.4.6.3.

19.4.4 Transmit and receive in-band and out-of-band spurious emissions

The ERP shall conform to in-band and out-of-band spurious emissions as set by the appropriate regulatory bodies for the 2.4 GHz band.

19.4.5 Slot time

The slot time is 20 µs, except that an optional 9 µs slot time may be used when the BSS consists of only ERP STAs capable of supporting this option. The optional 9 µs slot time shall not be used if the network has one or more NonERP STAs associated. For IBSS, the Short Slot Time subfield shall be set to 0, corresponding to a 20 µs slot time.

19.4.6 SIFS value

The ERP shall use a SIFS of 10 µs.

19.4.7 CCA performance

The CCA shall indicate true if there is no CCA “medium busy” indication. The CCA parameters are subject to the following criteria:

a) When a valid signal with a signal power of −76 dBm or greater at the receiver antenna connector is present at the start of the PHY slot, the receiver’s CCA indicator shall report the channel busy with probability $CCA_{Detect\_Probability}$ within a $CCA\_Time$. $CCA\_Time$ is $SlotTime$ −
RxTxTurnaroundTime. CCA_Detect_Probability is the probability that the CCA does respond correctly to a valid signal. The values for these parameters are found in Table 19-6. Note that the CCA Detect Probability and the power level are performance requirements.

b) In the event that a correct PLCP header is received, the ERP shall hold the CCA signal inactive (channel busy) for the full duration, as indicated by the PLCP LENGTH field. Should a loss of CS occur in the middle of reception, the CCA shall indicate a busy medium for the intended duration of the transmitted PPDU.

19.4.8 PMD transmit specifications

19.4.8.1 General

The PMD transmit specifications shall follow 18.3.9 with the exception of the transmit power level (18.3.9.2), the transmit center frequency tolerance (18.3.9.5), the symbol clock frequency tolerance (18.3.9.6), and the time of departure accuracy (18.3.9.9). Regulatory requirements may have an effect on the combination of maximum transmit power and spectral mask if the resulting signals violate restricted band emission limits.

19.4.8.2 Transmit power levels

The maximum transmit power level shall meet the requirements of the local regulatory body.

19.4.8.3 Transmit center frequency tolerance

The transmit center frequency tolerance shall be ± 25 PPM maximum. The transmit center frequency and symbol clock frequency shall be derived from the same reference oscillator (locked).

19.4.8.4 Symbol clock frequency tolerance

The symbol clock frequency tolerance shall be ± 25 PPM maximum. The transmit center frequency and symbol clock frequency shall be derived from the same reference oscillator (locked oscillators). This means that the error in PPM for the carrier and the symbol timing shall be the same.

19.4.8.5 Time of Departure accuracy

The time of departure specifications shall follow 18.3.9.9 for PPDUs transmitted using ERP-OFDM format and 17.4.7.10 for PPDUs transmitted using ERP-DSSS/CCK, ERP-PBCC, and DSSS-OFDM formats.
19.5 ERP operation specifications

19.5.1 General

Subclause 19.5 describes the receive specifications for the PMD sublayer. The receive specification for the ERP-OFDM modes shall follow 18.3.10 with the exception of the receiver maximum input level (18.3.10.5) and the adjacent channel rejection (18.3.10.3). The receive specifications for the ERP-DSSS modes shall follow 17.4.8 with the exception of the receiver maximum input level (17.4.8.3).

19.5.2 Receiver minimum input level sensitivity

The PER of the ERP-OFDM modes shall be less than 10% at a PSDU length of 1000 octets for the input levels of Table 18-14 of 18.3.10. Input levels are specific for each data rate and are measured at the antenna connector. A noise figure of 10 dB and an implementation loss of 5 dB are assumed. The PER of the ERP-DSSS modes shall be as specified in 17.4.8.2.

19.5.3 Adjacent channel rejection

Adjacent channels at 2.4 GHz are defined to be at ± 25 MHz spacing. The adjacent channel rejection shall be measured by setting the desired signal’s strength 3 dB above the rate-dependent sensitivity specified in Table 18-14 of 18.3.10 and raising the power of the interfering signal until 10% PER is caused for a PSDU length of 1000 octets. The power difference between the interfering and the desired channel is the corresponding adjacent channel rejection. The interfering signal in the adjacent channel shall be a conformant OFDM signal, unsynchronized with the signal in the channel under test. For an OFDM PHY, the corresponding rejection shall be no less than specified in Table 18-14 of 18.3.10.

The alternative adjacent channel rejection of Table 18-14 shall not be required for the ERP.

The adjacent channel rejection of the ERP-DSSS modes shall follow 17.4.8.4.

19.5.4 Receive maximum input level capability

The PER shall be less than 10% at a PSDU length of 1000 octets for an input level of –20 dBm measured at the antenna connector for any supported modulation signal or data rate (i.e., 1, 2, 5.5, 6, 9, 11, 12, 18, 22, 24, 33, 36, 48, 54 Mb/s).

19.5.5 Transmit spectral mask

The transmit spectral mask for the ERP-OFDM modes shall follow 18.3.9.3 and is shown in Figure 18-13 therein. The transmit spectral mask for the ERP-DSSS modes shall follow 17.4.7.4 and is shown in Figure 17-18 therein.

19.6 ERP-PBCC operation specifications

19.6.1 General

The ERP-PBCC receiver specifications shall follow 17.4.8 except as noted.

These optional modes provide systems with the ability to achieve data rates of 22 Mb/s and 33 Mb/s in modes that are fully backwards compatible with Clause 16 and Clause 17 BSSs without requiring additional coordination or protection mechanisms. In addition, the 22 Mb/s ERP-PBCC mode is spectrally identical to Clause 17 BSSs. Four optional ERP-PBCC modulation formats and data rates are specified for the ERP. They shall be based on PBCC 5.5, 11, 22, and 33 Mb/s modulations. The rates of 5.5 Mb/s and 11 Mb/s are
described in 17.4.6.7.

19.6.2 Receiver minimum input level sensitivity

For the 22 Mb/s ERP-PBCC mode, the frame error ratio shall be less than $8 \times 10^{-2}$ at a PSDU length of 1024 octets for an input level of $-76$ dBm measured at the antenna connector. For the 33 Mb/s ERP-PBCC mode, the corresponding input level shall be $-74$ dBm.

19.6.3 Receiver adjacent channel rejection

The adjacent channel rejection shall be equal to or better than 35 dB, with an FER of $8 \times 10^{-2}$ using ERP-PBCC modulation and a PSDU length of 1024 octets. The adjacent channel rejection shall be measured using the following method. Input an ERP-PBCC modulated signal of the same rate at a level 6 dB greater than specified in 19.6.2. In an adjacent channel (25 MHz separation as defined by the channel numbering), input a signal modulated in a similar fashion, which adheres to the transmit mask specified in 17.4.7.4, to a level 41 dB above the level specified in 19.6.2. The adjacent channel signal shall be derived from a separate signal source. It shall not be a frequency-shifted version of the reference channel. Under these conditions, the FER shall be no worse than $8 \times 10^{-2}$.

19.7 DSSS-OFDM operation specifications

19.7.1 General

This optional mode provides systems with the ability to use OFDM in a mode that is fully compatible with Clause 16 and Clause 17 BSSs without requiring additional coordination. That is, it does not need a protection mechanism. This compatibility requires the use of Clause 17 long and short preambles and inclusion of a signal extension field to match SIFS spacing of Clause 17 systems. By reusing the Clause 17 preambles, this optional mode ensures that the Clause 17 CCA and SIFS interval function properly when ERP and NonERP STAs interoperate. When this option is enabled, the same rates shall be supported in both ERP-OFDM and DSSS-OFDM. The DSSS-OFDM PMD transmit and receive specifications shall follow the related ERP-OFDM specifications in 19.5.

19.7.2 Overview

This optional extension of the DSSS system builds on the payload data rates of 1, 2, 5.5, and 11 Mb/s, as described in Clause 17, to provide 6, 9, 12, 18, 24, 36, 48, and 54 Mb/s payload data rates while reusing the preambles (short and long) described by Clause 17. The capability described in this subclause is called DSSS-OFDM. This optional capability complements the Extended Rate OFDM mode described in Clause 19 by combining OFDM modulation with DSSS preambles. As a result, for DSSS-OFDM, the PPDU format described in 17.2.2 is relatively unchanged. The major change is to the format of the PSDU. The Clause 17 single carrier PSDU is replaced by a PSDU that is very similar to the PSDUs described in Clause 18. This subclause highlights the differences. In addition, 19.7.3 specifies the radio and physical layer behavior of the transition from the Barker symbol-modulated preamble and the OFDM-modulated data for PSDU.

19.7.3 Single carrier to multicarrier transition requirements

19.7.3.1 General

The spectrum mask for the DSSS-OFDM waveform shall meet the requirements as shown in Figure 18-13 of 18.3.9.3.
The single carrier signal segment of the packet shall have a coherent relationship with the multicarrier (OFDM) segment of the packet. All characteristics of the signal shall be transferable from one symbol to the next, even when transitioning to the OFDM segment. This enables high-performance, coherent receiver operation across the whole packet. This requirement is no different in nature than that stated in Clause 16, Clause 18, and Clause 17. The distinction is that those clauses use a signaling scheme that is either just single carrier or just multicarrier. In contrast, for this mode, both single carrier signaling and multicarrier signaling are used within the context of a single packet.

This subclause specifies the coherent relationship between the single carrier segment and the OFDM segment, so that the receiver has the opportunity to track through the transition without any forced parameter reacquisition. The single carrier preamble and header provide all parametric information required for demodulation of the OFDM segment to within conventional estimation-in-noise accuracy. Although multicarrier sync features are provided for convenience at OFDM segment onset, if and how to use the multicarrier sync for reacquisition is an implementer’s decision. Multicarrier sync is not necessary. The packet is coherent throughout.

As shown in Figure 19-7, the ideal transition would provide a constant carrier frequency and phase, a constant power, a constant spectrum, and a constant timing relationship. Constant in this context means that the same clock crystal that sets the frequencies and timing of each part is the same through the transition. This allows the frequency and timing tracking loops to work undisturbed through the transition. Subclauses 19.7.3.2 to 19.7.3.7 establish the ideal transition characteristics for the transmit signal. Subclause 19.7.3.8 specifies the required implementation fidelity or accuracy.

![Ideal Transition Specification](image)

**Figure 19-7—Single carrier to multicable carrier transition definition**

19.7.3.2 Spectral binding requirement

19.7.3.2.1 General

The spectral binding requirement allows the receiver’s estimate of the channel state information to be transferred from the single carrier packet segment to the multicarrier packet segment. This requirement establishes a coherent relationship between the end-to-end frequency responses of the single carrier and multicarrier segments.

During reception of the single carrier preamble and header, the receiver may estimate the channel impulse response. In practice, this could be accomplished through Barker code correlation. The channel impulse response contains end-to-end frequency response information about the linear distortion experienced by the signal due to filters and multipath. This distortion might be mitigated with an equalizer or other commonly known techniques.
The channel impulse response estimate generated during the single carrier packet segment includes the single carrier’s pulse-shaping, filter frequency response used to control the single carrier’s transmit spectrum and transmit impulse response. The single carrier’s pulse-shaping filter may be distinct from the shaping technique used for the multicarrier segment.

The spectral binding requirement states that the linear distortions experienced by the single carrier signal and the linear distortions experienced by the multicarrier signal have a known relationship. This relationship is defined by this specification and shall be manifested by all compliant transmit radios. This allows any receiver to exploit channel information derived during the single carrier segment and reuse the channel information during the multicarrier segment, if desired.

Three elements have been itemized for this specification to achieve spectral binding. All three elements are necessary to achieve spectral binding, and they are discussed in the next three subclauses. The first element focuses on distortions common to both the single carrier packet segment and the multicarrier packet segment. The second element deals with pulse-shaping unique to the OFDM packet segment. The third element deals with pulse-shaping unique to the single carrier packet segment. The multicarrier pulse shape discussion precedes the single carrier’s pulse shape discussion because it is believed this is a more comfortable progression, due to similar multicarrier pulse-shaping considerations contained in Clause 18.

### 19.7.3.2.2 Common linear distortions

Separate from the single carrier and the multicarrier pulse shaping, transmit signal generation is designed to provide linear distortion continuity to the receiver’s demodulation algorithms. The common linear distortion requirement is illustrated in Figure 19-8, where it is shown that the processing at the receiver assumes that the dominant linear distortions are induced on all waveform segments. The receiver observes the composite linear distortion due to imperfect transmit radio filters, due to multipath filtering, and due to imperfect receive radio filters. In general, the receiver is unable to decompose the distortion into separate physical components and is only able to observe the aggregate effect. This specification constrains only the linear distortions in the transmit radio, because that is what is necessary to ensure interoperability. The soft switch that appears in Figure 19-8 is a conceptual element to implement the transition, as described below.

![Figure 19-8 — Linear distortions common to the single carrier and multicarrier signal segments](image)

In short, this common linear distortion requirement states that the dominant filters in the transmit radio stay invariant and common to all waveform segments. Once the receiver has determined the end-to-end impulse response, channel information is assumed to be common to both the single carrier signal and the multicarrier signal. This enables receiver design of linear-distortion mitigation techniques that do not require a reacquisition after transitioning to OFDM.
19.7.3.2.3 Symbol shaping unique to the DSSS-OFDM segment

OFDM spectral shaping may be achieved using two mechanisms: (1) Time-domain convolution filtering may be used to shape the spectrum. (2) Time-domain window tapering of OFDM symbol onset and termination may be used to shape the spectrum. This second mechanism can be viewed as frequency domain convolution. The first mechanism shall be common to both the OFDM and single carrier if it is a dominant distortion mechanism. The second mechanism may be unique to the OFDM segment, because it does not affect the frequency response of the 52 subcarriers.

The first spectral shaping mechanism using time-domain convolution filtering shall be common to both the single carrier and multicarrier segments for the reasons described in the preceding section. The receiver should not see intrapacket frequency response discontinuities.

Convolution filtering may be budgeted in various ways. One option would be to use a single filter that both the single carrier and multicarrier segments use. Another option would be to use two different physical filter realizations, one for the single carrier segment and a second for the multicarrier segment, say, for reason of distinct sample rates or bit precision. With this second implementation option, the designer shall ensure the frequency response of the filter is common to both packet segments.

The second shaping mechanism, which uses frequency-domain convolution through time-domain subcarrier onset-and-termination shaping, may be unique to the OFDM segment. This unique technique is acceptable because it does not modify the required frequency response of the 52 subcarriers.

Spectral shaping by tapering the OFDM symbol onset-and-termination using a time-domain window is described in Clause 18 and is equally germane to Clause 19 systems. For convenience, one of the relevant figures from Clause 18 is repeated here as Figure 19-9. Clause 18 suggested that the tapering transition duration is 0.1 µs.

![Diagram](image-url)
The effect of time-domain windowing on a single subcarrier’s power spectrum is shown in Figure 19-10 for two cases. The first case is rectangular time-domain windowing of an OFDM symbol. The second case is for the Clause 18 suggested time-domain windowing of an OFDM symbol with a 0.1 µs transition. Note the difference in frequency-dependent amplitude roll-off. Adding the 52 frequency-bin-centered individual subcarrier power spectral densities generates the composite 52 subcarrier power spectrum.

![Subcarrier spectrums for rectangular windowing and Clause 18 suggested windowing](image)

Figure 19-10—Subcarrier spectrums for rectangular windowing and Clause 18 suggested windowing

This type of OFDM spectrum control does not affect the relative amplitudes and phases of the individual subcarriers. Instead, it affects each subcarrier’s power spectral density. Consequently, this type of spectrum control has a benign effect on the relative spectrums of single carrier and the multicarrier packet segments.

To achieve the design goal, the implementer may budget spectral shaping in the transmit radio. Some of the spectral shaping may be achieved using time-domain convolution filtering, and some may be achieved through time-domain windowing of the OFDM. In any case, the transmit implementation shall provide frequency response coherency.

### 19.7.3.2.4 Pulse shaping unique to the single carrier segment

This subclause describes the pulse-shaping requirements of the single carrier segment of the DSSS-OFDM packet. To establish frequency response coherency, it is necessary to specify the frequency response of the single carrier signal that establishes a coherent relationship to the frequency response of the OFDM.

The frequency response of the single carrier pulse is patterned after the tandem OFDM. The pattern is the OFDM signal as described in Clause 18, with an example provided in Annex L. The ideal OFDM signal has a flat amplitude response and zero-phase offset across 52 subcarriers. Clause 18 establishes the ideal frequency-response relationship among the 12 short SYNC subcarriers, 52 long SYNC subcarriers, the 52 SIGNAL field subcarriers, and the 52 data field subcarriers. Similarly, the ideal relationship to the single carrier frequency response is defined.

Relative to the ideal OFDM, the single carrier part of the DSSS-OFDM signal shall have the pulse shape established herein. In a particular implementation, it is acceptable to deviate from this ideal but only in a manner that is common to both the single carrier signal and the multicarrier signal across the passband of the OFDM signal. This requirement provides the required frequency response coherency.
The frequency response of the single carrier pulse is patterned after the OFDM that is transmitted in tandem. The single carrier pulse is derived from a time-windowed sinc function as shown in Figure 19-11 and Equation (19-3). The sinc function is the time response of an ideal brickwall filter. The brickwall filter is set equal to the bandwidth of an ideal OFDM signal. In particular, the bandwidth of the brickwall filter has been set to 52 times the Clause 18 subcarrier spacing of 20/64 MHz, or 312.5 KHz.

\[ f_{W} = 52 \times \frac{20}{64} \text{ MHz} \]

The infinite duration impulse response of the brickwall filter should be windowed to something practical. A continuous time version of the Hanning window may be used. The Hanning window and an overlay of the sinc function are shown in Equation (19-4) and Figure 19-12.

\[ h_{Window}(t) = 0.5 \left[ 1 + \cos \left( \frac{2 \pi t}{T_{\text{SPAN}}} \right) \right] \]

where

\[ T_{\text{SPAN}} = 0.8 \mu s \]
The pulse specified for use with the single carrier packet segment is obtained by application of the window as shown in Equation (19-5) and Figure 19-13. Notice that its duration is equal to a Clause 18 short sync cycle, only 0.8 µs.

\[ p(t) = h_{\text{Window}} h_{\text{IdealBW}}(t) \]  

(19-5)

The frequency response of the derived pulse is shown in Figure 19-14. This pulse generates a single carrier signal that has a spectrum nearly equal to that of the OFDM signal. This means that the receiver experiences essentially no change in receive signal power behavior even in the presence of multipath. At the point of the outermost subcarrier in the OFDM signal, the single carrier spectrum is down only about 4 dB. This is deemed adequate because the single carrier preamble-header is long in duration compared to the Clause 18 sync duration. Plenty of time is available to generate channel impulse response information that is sufficiently accurate.
In summary, the specified single carrier pulse provides frequency response coherency between the single carrier and multicarrier segments of the packet. This does not mean that the spectrums are identical between segments. Rather, it means the ideal frequency responses of both are known. Beyond this, all linear distortion is common to both. It is not necessary to use this single carrier pulse during Clause 16 or Clause 17 packet transmissions.

19.7.3.3 Sample-power matching requirement

The transmit signal power shall be equal for the single carrier and multicarrier signal segments. The point of comparison is shown in Figure 19-15. The power measurement shall be over the single carrier header and over the OFDM data symbols.

19.7.3.4 Transition time alignment

This subclause describes how the single carrier signal and the multicarrier signal are time aligned. The single carrier signal uses a chip rate of 11 MHz. The OFDM signal uses a fundamental sample rate of 20 MHz. The signals are easily aligned by first aligning the 11 MHz clock and the 20 MHz clock on 1 µs boundaries as shown in Figure 19-16.
The 11 Barker chips of the preamble and header are transmitted aligned with this timing epoch. The first Barker chip is transmitted synchronous to the epoch, and then the remaining 10 chips follow. This is repeated over the duration of the preamble and header.

The peak of the continuous-time single carrier pulse shall be aligned to this epoch as shown in Figure 19-17.

The first full-strength OFDM sample is sent on the 1 µs epoch boundary, as illustrated in Figure 19-17. Tapering may precede this. The peak corresponds to the first full-strength sample described in Annex L.
19.7.3.5 Single carrier termination

The single carrier segment of a packet should terminate in nominally 0.1 µs with the same type shaping described for Clause 18. This is depicted in Figure 19-18. It is not necessary to completely flush the single carrier pulse-shaping filter. This minimizes the transition time overhead. This is informative as the basic requirement is to meet the spectral mask defined in 18.3.9.3.

This termination may be performed explicitly in the baseband processor, or it may be provided by filters in the transmit radio.

19.7.3.6 Transition carrier frequency requirement

The carrier frequency shall be coherent across the packet segments. This effect is depicted in Figure 19-19.
19.7.3.7 Transition carrier phase requirement

The carrier phase shall be coherent across the single carrier to multicarrier transition. This coherency shall be differentially established relative to the phase of the last Barker symbol transmitted (the last 11 single carrier chips). The OFDM segment symbols shall be transmitted with one of four phases relative to the phase of OFDM symbols as described in Clause 18. These phases include 0, 90, 180, or 270 degrees, depending on the phase of the last Barker symbol. The phase of the first OFDM symbol (as referenced by the pilot tones) shall be 45 degrees more than the phase of the last Barker symbol. “More than” implies a clockwise rotation as shown in Figure 19-20.

![Figure 19-20](image)

In a transmit implementation using I/Q signaling, it is common to maximally energize in the I-and-Q channels concurrently for BPSK or QPSK signaling. The analog stages of the transmit radio tend to perform best with this configuration. To achieve this effect, typically the BPSK or QPSK I-and-Q alignment of the Barker symbols are at 45 degrees, 135 degrees, –135 degrees, and –45 degrees, as shown in Figure 19-21. This Barker symbol alignment is used to establish the phase of the OFDM signal.

![Figure 19-21](image)
Figure 19-20 is a series of diagrams illustrating the phase relationship between the last Barker symbol (not the last chip) in the header and subsequent OFDM symbols. For example, if the phase of the last Barker symbol is in the first quadrant at 45 degrees, then the phase of the OFDM symbols is as described in Annex L unmodified. However, if the phase of the last Barker symbol is in the second quadrant (135 degree phase), then the phase of the OFDM symbols is rotated by +90 degrees relative to the phase of the samples in Annex L. If the phase of the last Barker symbol is in the third quadrant (–135 degree phase), then the phase of the OFDM symbols is rotated by +180 degrees relative to the phase of the samples in Annex L. If the phase of the last Barker symbol is in the fourth quadrant (–45 degree phase), then the phase of the OFDM symbols is rotated by +270 degrees relative to the phase of the samples in Annex L.

If the transmitter generates the Barker symbols at some other angular relationship to the I/Q axes, then the OFDM symbols shall be transmitted at a phase 45 degrees more than the phase of the last 11-chip Barker symbol.

19.7.3.8 Transmit modulation accuracy requirement

The preceding subclauses establish transmit modulation requirements without mention of required accuracy. The accuracy is as described in 18.3.9.8.

The required accuracy for a given transmit packet is data rate dependent. The packet accuracy is set by the data rate of the OFDM portion of the packet. The preamble and header are transmitted with the same fidelity requirement as the fidelity requirement levied on the OFDM portion of the packet. For the single carrier portion of the packet, the EVM is interpreted as normalized mean-squared error.

19.8 ERP PLME

19.8.1 PLME SAP

Table 19-7 lists the additional MIB attributes that may be accessed by the PHY sublayer entities and the intralayer of higher LMEs. These attributes are accessed via the PLME_GET, PLME_SET, PLME_RESET, and PLME_CHARACTERISTICS primitives defined in 6.5.

19.8.2 MIB

High Rate PHY MIB attributes are defined in Annex C with additions from this supplement and with specific values defined in Table 19-7.

19.8.3 TXTIME

19.8.3.1 General

The value of TXTIME is calculated for each modulation type based on parameters in the TXVECTOR. For the 1, 2, 5.5, and 11 Mb/s modes with DSSS, CCK, and PBCC modulation formats, the value shall be calculated as described in 17.3.4.

19.8.3.2 ERP-OFDM TXTIME calculations

The value of the TXTIME parameter returned by the PLME_TXTIME.confirm primitive shall be calculated using the ERP-OFDM TXTIME calculation as shown in Equation (19-6).

\[
TXTIME = T_{\text{PREAMBLE}} + T_{\text{SIGNAL}} + T_{\text{SYM}} \times \text{Ceiling} \left( \frac{16 + 8 \times \text{LENGTH} + 6}{N_{\text{DBPS}}} \right) + \text{Signal Extension} \tag{19-6}
\]

where

\[T_{\text{PREAMBLE}}, T_{\text{SIGNAL}}, \text{ and } T_{\text{SYM}}\] are defined in Table 18-5 in 18.3.2.4.
is the number of data bits per symbol and is derived from the DATARATE parameter in Table 18-4 in 18.3.2.3

Ceiling is a function that returns the smallest integer value greater than or equal to its argument value

Signal Extension is 6 µs

19.8.3.3 ERP-PBCC TXTIME calculations

The value of the TXTIME parameter returned by the PLME_TXTIME.confirm primitive shall be calculated according to the following:

For PBCC 5.5 Mb/s and 11 Mb/s, see 17.3.4.

For ERP-PBCC-22 Mb/s, use Equation (19-7).

\[
TXTIME = \text{PreambleLength} + \text{PLCPHeaderTime} + \text{Ceiling}(((\text{LENGTH}+\text{PBCC}) \times 8) / \text{DATARATE})
\]

(19-7)

For ERP-PBCC-33 Mb/s, use Equation (19-8).

\[
TXTIME = \text{PreambleLength} + \text{PLCPHeaderTime} + \text{Ceiling}(((\text{LENGTH}+\text{PBCC}) \times 8) / \text{DATARATE}) + \text{ClkSwitchTime}
\]

(19-8)

where

- LENGTH and DATARATE are values from the TXVECTOR parameter of the corresponding PLME_TXTIME request primitive
- PBCC has a value of 1 if the SIGNAL value from the TXVECTOR parameter specifies ERP-PBCC and has a value of 0 otherwise
- PreambleLength is 144 µs if the PREAMBLE_TYPE value from the TXVECTOR parameter indicates “LONGPREAMBLE,” or 72 µs if the PREAMBLE_TYPE value from the TXVECTOR parameter indicates “SHORTPREAMBLE”
- PLCPHeaderTime is 48 µs if the PREAMBLE_TYPE value from the TXVECTOR parameter indicates “LONGPREAMBLE,” or 24 µs if the PREAMBLE_TYPE value from the TXVECTOR parameter indicates “SHORTPREAMBLE”
- LENGTH is in units of octets
- DATARATE is in units of Mb/s
- ClkSwitchTime is defined as 1 µs
- Ceiling is a function that returns the smallest integer value greater than or equal to its argument value

19.8.3.4 DSSS-OFDM TXTIME calculations

The value of the TXTIME parameter returned by the PLME_TXTIME.confirm primitive shall be calculated according to Equation (19-9):

\[
TXTIME = \text{PreambleLengthDSSS} + \text{PLCPHeaderTimeDSSS} + \text{PreambleLengthOFDM} + \text{PLCPSignalOFDM} + 4 \times \text{Ceiling}((\text{PLCPServiceBits} + 8 \times (\text{NumberOfOctets} + \text{PadBits}) / N_{DBPS}) + \text{SignalExtension}
\]

(19-9)

where

- PreambleLengthDSSS is 144 µs if the PREAMBLE_TYPE value from the TXVECTOR parameter indicates “LONGPREAMBLE,” or 72 µs if the PREAMBLE_TYPE value from the TXVECTOR parameter indicates “SHORTPREAMBLE”
PLCPHeaderTimeDSSS is 48 µs if the PREAMBLE_TYPE value from the TXVECTOR parameter indicates “LONGPREAMBLE,” or 24 µs if the PREAMBLE_TYPE value from the TXVECTOR parameter indicates “SHORTPREAMBLE”

Ceiling is a function that returns the smallest integer value greater than or equal to its argument value

PreambleLengthOFDM is 8 µs
PLCPSignalOFDM is 4 µs
PLCPServiceBits is 16 bits
NumberOfOctets is the number of data octets in the PSDU
PadBits is 6 bits
SignalExtension is 6 µs
$N_{DBPS}$ is the number of data bits per OFDM symbol

### 19.8.4 ERP-OFDM PLCP PSDU definition

The DSSS PHY characteristics in Table 19-8 shall be used for the ERP for the purposes of MAC timing calculations.

The slot time shall be 20 µs, unless the BSS consists only of ERP STAs that support the Short Slot Time option. STAs indicate support for a short slot time by setting the Short Slot Time subfield to 1 when transmitting Association Request and Reassociation Request MMPDUs. If the BSS consists of only ERP STAs that support the Short Slot Time option, an optional 9 µs slot time may be used. APs indicate usage of a 9 µs slot time by setting the Short Slot Time subfield to 1 in all Beacon, Probe Response, Association Response, and Reassociation MMPDU transmissions as described in 8.4.1.4. STAs shall use short slot if the BSS indicates short slot.

### 19.9 Extended rate PMD sublayer

#### 19.9.1 Scope and field of application

This subclause describes the PMD services provided to the PLCP for the ERP.

#### 19.9.2 Overview of service

The ERP sublayer accepts PLCP sublayer service primitives and provides the actual means by which data are transmitted or received from the medium. The combined functions of the Extended Rate PMD sublayer primitives and parameters for the receive function result in a data stream, timing information, and associated received signal parameters being delivered to the PLCP sublayer. A similar functionality is provided for data transmission.

#### 19.9.3 Overview of Interactions

The primitives associated with the PLCP sublayer to the ERP fall into two basic categories, as follows:

a) Service primitives that support PLCP peer-to-peer interactions

b) Service primitives that have local significance and that support sublayer-to-sublayer interactions

#### 19.9.4 Basic service and options

##### 19.9.4.1 General

All of the service primitives described in this subclause are considered mandatory, unless otherwise specified.

##### 19.9.4.2 PMD_SAP peer-to-peer service primitives

Table 19-9 indicates the primitives for peer-to-peer interactions.

19.9.5 PMD_SAP detailed service specification

19.9.5.1 Introduction

Subclauses 19.9.5.2 to 19.9.5.14 describe the services provided by each PMD primitive.

19.9.5.2 PMD_DATA.request

This primitive is the same as that defined in 18.5.5.2 and 17.4.5.2 except that the parameter TXD_UNIT is expanded in scope to reflect the supported modulation formats of ERP as defined in 19.9.4.4.

19.9.5.3 PMD_DATA.indication

This primitive is the same as that defined in 18.5.5.3 and 17.4.5.3 except that the parameter RXD_UNIT is expanded in scope to reflect the supported modulation formats of ERP as defined in 19.9.4.4.

19.9.5.4 PMD_MODULATION.request

This primitive is the same as that defined in 17.4.5.4 except that the parameter MODULATION is expanded in scope to reflect the supported modulation formats of ERP as defined in 19.9.4.4.

19.9.5.5 PMD_PREAMBLE.request

This primitive is the same as that defined in 17.4.5.5, including the definition of the parameter PREAMBLE. This primitive is not used in association with transmission of ERP-OFDM modulations.

---

</tr>
</tbody>
</table>
19.9.5.6 PMD_TXSTART.request

This primitive is the same as that defined in 18.5.5.4 and 17.4.5.7.

19.9.5.7 PMD_TXEND.request

This primitive is the same as that defined in 18.5.5.5 and 17.4.5.8.

19.9.5.8 PMD_ANTSEL.request

This primitive is the same as that defined in 17.4.5.9, including the definition of the parameter ANT_STATE.

19.9.5.9 PMD_TXPRWLVL.request

This primitive is the same as that defined in 18.5.5.6, including the definition of the parameter TXPWR_LEVEL.

19.9.5.10 PMD_RATE.request

This primitive is the same as that defined in 18.5.5.7 and 17.4.5.11, except that the parameter RATE is expanded in scope to reflect the supported ERP transmission rates as defined in 19.9.4.4.

19.9.5.11 PMD_RSSI.indication

This primitive is the same as that defined in 18.5.5.8 and 17.4.5.12, including the parameter RSSI. This primitive is used to aid in link optimization algorithms such as roaming decisions.

19.9.5.12 PMD_SQ.indication

This primitive is the same as that defined in 17.4.5.13, including the parameter SQ. This primitive is not used in association with reception of ERP-OFDM modulations. This primitive is used to aid in link optimization algorithms such as roaming decisions.

19.9.5.13 PMD_CS.indication

This primitive is the same as that defined in 17.4.5.14, except that its use is expanded for use with all ERP modulation types as described in 19.3.5.

19.9.5.14 PMD_ED.indication

This primitive is the same as that defined in 17.4.5.15, except that its use is expanded for use with all ERP modulation types as described in 19.3.5.

19.9.5.15 PMD_RCPI.indication

This primitive is the same as that defined in 18.5.5.9 and 17.4.5.17, including the parameter RCPI. This primitive is used for radio measurement purposes and to aid in link optimization algorithms such as roaming decisions.
20. High Throughput (HT) PHY specification

20.1 Introduction

20.1.1 Introduction to the HT PHY

Clause 20 specifies the PHY entity for a high throughput (HT) orthogonal frequency division multiplexing (OFDM) system.

In addition to the requirements found in Clause 20, an HT STA shall be capable of transmitting and receiving frames that are compliant with the mandatory PHY specifications defined as follows:

- In Clause 18 when the HT STA is operating in a 20 MHz channel width in the 5 GHz band
- In Clause 17 and Clause 19 when the HT STA is operating in a 20 MHz channel width in the 2.4 GHz band

The HT PHY is based on the OFDM PHY defined in Clause 18, with extensibility up to four spatial streams, operating in 20 MHz bandwidth. Additionally, transmission using one to four spatial streams is defined for operation in 40 MHz bandwidth. These features are capable of supporting data rates up to 600 Mb/s (four spatial streams, 40 MHz bandwidth).

The HT PHY data subcarriers are modulated using binary phase shift keying (BPSK), quadrature phase shift keying (QPSK), 16-quadrature amplitude modulation (16-QAM), or 64-QAM. Forward error correction (FEC) coding (convolutional coding) is used with a coding rate of 1/2, 2/3, 3/4, or 5/6. LDPC codes are added as an optional feature.

Other optional features at both transmit and receive sides are 400 ns short guard interval (GI), transmit beamforming, HT-greenfield format, and STBC.

An HT non-AP STA shall support all equal modulation (EQM) rates for one spatial stream (MCSs 0 to 7) using 20 MHz channel width. An HT AP shall support all EQM rates for one and two spatial streams (MCSs 0 to 15) using 20 MHz channel width.

The maximum HT PSDU length is 65 535 octets.

20.1.2 Scope

The services provided to the MAC by the HT PHY consist of two protocol functions, defined as follows:

a) A PHY convergence function, which adapts the capabilities of the physical medium dependent (PMD) system to the PHY service. This function is supported by the physical layer convergence procedure (PLCP), which defines a method of mapping the PSDUs into a framing format (PPDU) suitable for sending and receiving PSDUs between two or more STAs using the associated PMD system.

b) A PMD system whose function defines the characteristics and method of transmitting and receiving data through a wireless medium between two or more STAs. Depending on the PPDU format, these STAs support a mixture of HT PHY and Clause 16, Clause 18, Clause 17, or Clause 19 PHYs.

20.1.3 HT PHY functions

20.1.3.1 General

The HT PHY contains three functional entities: the PHY convergence function (i.e., the PLCP), the PMD function, and the layer management function (i.e., the PLME). Each of these functions is described in detail.
in 20.3 through 20.5.

The HT PHY service is provided to the MAC through the PHY service primitives defined in Clause 7.

20.1.3.2 HT PLCP sublayer

In order to allow the MAC to operate with minimum dependence on the PMD sublayer, a PHY convergence sublayer is defined (i.e., the PLCP). The PLCP sublayer simplifies the PHY service interface to the MAC services.

20.1.3.3 HT PMD sublayer

The HT PMD sublayer provides a means to send and receive data between two or more STAs. This clause is concerned with the 2.4 GHz and 5 GHz frequency bands using HT OFDM modulation.

20.1.3.4 PHY management entity (PLME)

The PLME performs management of the local PHY functions in conjunction with the MLME.

20.1.3.5 Service specification method

The models represented by figures and state diagrams are intended to be illustrations of the functions provided. It is important to distinguish between a model and a real implementation. The models are optimized for simplicity and clarity of presentation; the actual method of implementation is left to the discretion of the HT-PHY-compliant developer. The service of a layer or sublayer is the set of capabilities that it offers to a user in the next higher layer (or sublayer). Abstract services are specified here by describing the service primitives and parameters that characterize each service. This definition is independent of any particular implementation.

20.1.4 PPDU formats

The structure of the PPDU transmitted by an HT STA is determined by the TXVECTOR FORMAT, CH_BANDWIDTH, CH_OFFSET, and MCS parameters as defined in Table 20-1. The effect of the CH_BANDWIDTH, CH_OFFSET, and MCS parameters on PPDU format is described in 20.2.3.

The FORMAT parameter determines the overall structure of the PPDU as follows:

- **Non-HT format (NON_HT):** Packets of this format are structured according to the Clause 18 (OFDM) or Clause 19 (ERP) specification. Support for non-HT format is mandatory.

- **HT-mixed format (HT_MF):** Packets of this format contain a preamble compatible with Clause 18 and Clause 19 receivers. The non-HT-STF (L-STF), the non-HT-LTF (L-LTF), and the non-HT SIGNAL field (L-SIG) are defined so they can be decoded by non-HT Clause 18 and Clause 19 STAs. The rest of the packet cannot be decoded by Clause 18 or Clause 19 STAs. Support for HT-mixed format is mandatory.

- **HT-greenfield format (HT_GF):** HT packets of this format do not contain a non-HT compatible part. Support for HT-greenfield format is optional. An HT STA that does not support the reception of an HT-greenfield format packet shall be able to detect that an HT-greenfield format packet is an HT transmission (as opposed to a non-HT transmission). In this case, the receiver shall decode the HT-SIG and determine whether the HT-SIG cyclic redundancy check (CRC) passes.
20.2 HT PHY service interface

20.2.1 Introduction

The PHY interfaces to the MAC through the TXVECTOR, TXSTATUS, RXVECTOR, and PHYCONFIG_VECTOR. The TXVECTOR supplies the PHY with per-packet transmit parameters. Status of the transmission is reported from PHY to MAC by parameters within TXSTATUS. Using the RXVECTOR, the PHY informs the MAC of the received packet parameters. Using the PHYCONFIG_VECTOR, the MAC configures the PHY for operation, independent of frame transmission or reception.

This interface is an extension of the generic PHY service interface defined in 7.3.4.

20.2.2 TXVECTOR and RXVECTOR parameters

The parameters in Table 20-1 are defined as part of the TXVECTOR parameter list in the PHY-TXSTART.request primitive and/or as part of the RXVECTOR parameter list in the PHY-RXSTART.indication primitive.

### Table 20-1—TXVECTOR and RXVECTOR parameters  
(continued)

| Parameter       | Condition | Value                                                                 | TXVECTOR | RXVECTOR | See  
|-----------------|-----------|-----------------------------------------------------------------------|----------|----------|------
| LSIGVALID       | FORMAT is HT_MF | Indicates the data rate value that is in the L-SIG. This use is defined in 9.23.4. | Y        | Y        |      
|                 | FORMAT is HT_GF | Not present                                                           | N        | N        |      
|                 | FORMAT is HT_MF | True if L-SIG Parity is valid                                         | N        | Y        |      
|                 | Otherwise     | Not present                                                           | N        | N        |      
| SERVICE         | FORMAT is HT_MF or HT_GF | Scrambler initialization, 7 null bits + 9 reserved null bits | Y        | N        |      
|                 | Otherwise     | Not present                                                           | N        | N        |      
| TXPWR_LEVEL     |               | The allowed values for the TXPWR_LEVEL parameter are in the range from 1 to 8. This parameter is used to indicate which of the available TxpPowerLevel attributes defined in the MIB shall be used for the current transmission. | Y        | N        |      
| RSSI            |               | The allowed values for the RSSI parameter are in the range from 0 to RSSI maximum. This parameter is a measure by the PHY of the power observed at the antennas used to receive the current PPDU. RSSI shall be measured during the reception of the PLCP preamble. In HT-mixed format, the reported RSSI shall be measured during the reception of the HT-LTFs. RSSI is intended to be used in a relative manner, and it shall be a monotonically increasing function of the received power. | N        | Y        |      

NOTE 1: See Table 19-1 for definitions of formats.

20.2.3 Effect of CH_BANDWIDTH, CH_OFFSET, and MCS parameters on PPDU format

The structure of the PPDU transmitted by an HT STA is determined by the TXVECTOR FORMAT, CH_BANDWIDTH, CH_OFFSET, and MCS parameters as defined in Table 20-1. The effect of the FORMAT parameter is described in 20.1.4.

The operation of the PHY in the frequency domain is determined by the CH_BANDWIDTH and CH_OFFSET parameters. Table 20-2 shows the combination of CH_BANDWIDTH and CH_OFFSET parameters that are supported.

### Table 20-2—PPDU format as a function of CH_BANDWIDTH and CH_OFFSET parameters

| HT_CBW20     | CH_OFF_20 or CH_OFFSET is not present: **20 MHz HT format**—A STA that has a 20 MHz operating channel width transmits an HT-mixed or HT-greenfield format packet of 20 MHz bandwidth with one to four spatial streams.  
  CH_OFF_40: *Not defined*  
  CH_OFF_20U: **40 MHz HT upper format**—The STA transmits an HT-mixed or HT-greenfield format packet of 20 MHz bandwidth with one to four spatial streams in the upper 20 MHz of a 40 MHz channel.  
  CH_OFF_20L: **40 MHz HT lower format**—The STA transmits an HT-mixed or HT-greenfield format packet of 20 MHz bandwidth with one to four spatial streams in the lower 20 MHz of a 40 MHz channel. |
| HT_CBW40     | Not present: *Not defined*  
  CH_OFF_40: *Not defined*  
  CH_OFF_20U: **40 MHz non-HT upper format**—The STA transmits a non-HT packet of type ERP-DSSS, ERP-CCK, ERP-OFDM, ERP-PBCC, DSSS-OFDM, or OFDM in the upper 20 MHz of a 40 MHz channel.  
  CH_OFF_20L: *Not defined* |
| NON_HTCBW20  | CH_OFF_20 or CH_OFFSET is not present: **20 MHz non-HT format**—A STA that has a 20 MHz operating channel width transmits a non-HT format packet according to Clause 18 or Clause 19 operation.  
  CH_OFF_40: *Not defined*  
  CH_OFF_20U: **40 MHz non-HT upper format**—The STA transmits a non-HT packet of type ERP-DSSS, ERP-CCK, ERP-OFDM, ERP-PBCC, DSSS-OFDM, or OFDM in the upper 20 MHz of a 40 MHz channel.  
  CH_OFF_20L: **40 MHz non-HT lower format**—The STA transmits a non-HT packet of type ERP-DSSS, ERP-CCK, ERP-OFDM, ERP-PBCC, DSSS-OFDM, or OFDM in the lower 20 MHz of a 40 MHz channel. |
NOTE—Support of 20 MHz non-HT format and 20 MHz HT format with one and two spatial streams is mandatory at APs. Support of 20 MHz non-HT format and 20 MHz HT format with one spatial stream is mandatory at non-AP STAs.

### 20.2.4 Support for NON_HT formats

When the FORMAT parameter is equal to NON_HT, the behavior of the HT PHY is defined in other clauses as shown in Table 20-3, dependent on the operational band. In this case, the PHY-TXSTART.request primitive is handled by mapping the TXVECTOR parameters as defined in Table 20-3 and following the operation as defined in the referenced clause. Likewise the PHY-RXSTART.indication primitive emitted when a NON_HT PPDU is received is defined in the referenced clauses, with mapping of RXVECTOR parameters as defined in Table 20-3.

Non-HT format PPDUs structured according to Clause 16, Clause 18, Clause 17, or Clause 19 are transmitted:

- Within the limits of the transmit spectrum mask specified in the respective clauses, or
- As non-HT duplicate PPDUs within the limits of the 40 MHz transmit spectrum mask defined in 20.3.20.1, or
- As 20 MHz format non-HT PPDUs, within the limits of the 40 MHz transmit spectrum mask defined in 20.3.20.1, in the upper (CH_BANDWIDTH of value NON_HT_CBW20 and CH_OFFSET of value CH_OFF_20U) or lower (CH_BANDWIDTH of value NON_HT_CBW20 and CH_OFFSET of value CH_OFF_20U) 20 MHz of the 40 MHz channel.

Non-HT PPDUs transmitted using the 40 MHz transmit spectrum mask are referred to as 40 MHz mask non-HT PPDUs. Refer to 10.15.9 for CCA sensing rules for transmission of 40 MHz mask non-HT PPDUs.
20.2.5 TXSTATUS parameters

The parameters listed in Table 20-4 are defined as part of the TXSTATUS parameter list in the PHY-TXSTART.confirm(TXSTATUS) service primitive.

</tr>
</tbody>
</table>

20.3 HT PLCP sublayer

20.3.1 Introduction

A convergence procedure, in which PSDUs are converted to and from PPDU, is provided for the HT PHY in 20.3. During transmission, the PSDU is processed (i.e., scrambled and coded) and appended to the PLCP preamble to create the PPDU. At the receiver, the PLCP preamble is processed to aid in demodulation and delivery of the PSDU.

Two preamble formats are defined. For HT-mixed format operation, the preamble has a non-HT portion and an HT portion. The non-HT portion of the HT-mixed format preamble enables detection of the PPDU and acquisition of carrier frequency and timing by both HT STAs and STAs that are compliant with Clause 18 and/or Clause 19. The non-HT portion of the HT-mixed format preamble also consists of the SIGNAL field defined in Clause 18 and is thus decodable by STAs compliant with Clause 18 and Clause 19 as well as HT STAs.

The HT portion of the HT-mixed format preamble enables estimation of the MIMO channel to support demodulation of the HT data by HT STAs. The HT portion of the HT-mixed format preamble also includes the HT-SIG field, which supports HT operation. The SERVICE field is prepended to the PSDU.

For HT-greenfield operation, compatibility with Clause 18 and Clause 19 STAs is not required. Therefore, the non-HT portions of the preamble are not included in the HT-greenfield format preamble.

20.3.2 PPDU format

Two formats are defined for the PLCP: HT-mixed format and HT-greenfield format. These two formats are called *HT formats*. Figure 20-1 shows the non-HT format\(^{42}\) and the HT formats. There is also an MCS 32 format (specified in 20.3.11.11.5) used for MCS 32 that provides the lowest rate in a 40 MHz channel. In

---

\(^{42}\) The non-HT format is shown related to the terminology of this subclause. The non-HT PPDU format is defined in 18.3.3 and 18.3.2.
addition to the HT formats, there is a non-HT duplicate format (specified in 20.3.11.12) that duplicates the 20 MHz non-HT packet in two 20 MHz halves of a 40 MHz channel.

The elements of the PLCP packet are summarized in Table 20-5.

### Table 20-5—Elements of the HT PLCP packet

</tr>
<tr>
<td>Data</td>
<td>The Data field includes the PSDU</td>
</tr>
</tbody>
</table>

The HT-SIG, HT-STF, HT-GF-STF, HT-LTF1, and HT-LTFs exist only in HT packets. In non-HT and non-HT duplicate formats only the L-STF, L-LTF, L-SIG, and Data fields exist.

In both HT-mixed format and HT-greenfield format frames, there are two types of HT-LTFs: Data HT-LTFs (HT-DLTFs) and Extension HT-LTFs (HT-ELTFs). HT-DLTFs are always included in HT PPDU to provide the necessary reference for the receiver to form a channel estimate that allows it to demodulate the data.
portion of the frame. The number of HT-DLTFs, $N_{HTDLTF}$, may be 1, 2, or 4 and is determined by the
count of space-time streams being transmitted in the frame (see Table 20-13). HT-ELTFs provide
additional reference in sounding PPDU so that the receiver can form an estimate of additional dimensions
of the channel beyond those that are used by the data portion of the frame. The number of HT-ELTFs,
$N_{HELT}$, may be 0, 1, 2, or 4 (see Table 20-14). PLCP preambles in which HT-DLTFs are followed by
HT-ELTFs are referred to as staggered preambles. The HT-mixed format and HT-greenfield format frames
shown in Figure 20-1 both contain staggered preambles for illustrative purposes.

Transmissions of frames with TXVECTOR parameter NO_SIG_EXTN equal to false are followed by a
period of no transmission for a duration of aSignalExtension µs. See 9.3.8.

A Signal Extension shall be present in a transmitted PPDU, based on the parameters of the TXVECTOR,
when the NO_SIG_EXTN parameter is equal to false and either of the following is true:

- The FORMAT parameter is equal to HT_MF or HT_GF.
- The FORMAT parameter is equal to NON_HT, and the NON_HT_MODULATION parameter is
equal to ERP-OFDM, DSSS-OFDM, or NON_HT_DUPOFDM.

A Signal Extension shall be assumed to be present (for the purpose of timing of PHY-RXEND.indication
and PHY-CCA.indication primitives, as described below and in 20.3.23) in a received PPDU when either of
the following is true, based on the determined parameter values of the RXVECTOR:

- The FORMAT parameter is equal to HT_MF or HT_GF.
- The FORMAT parameter is equal to NON_HT, and the NON_HT_MODULATION parameter is
equal to ERP-OFDM, DSSS-OFDM, or NON_HT_DUPOFDM.

A PPDU containing a Signal Extension is called a signal extended PPDU. When transmitting a signal
extended PPDU, the PHY-TXEND.indication primitive shall be emitted a period of aSignalExtension µs
after the end of the last symbol of the PPDU. When receiving a signal extended PPDU, the PHY-
RXEND.indication primitive shall be emitted a period of aSignalExtension µs after the end of the last
symbol of the PPDU.

20.3.3 Transmitter block diagram

HT-mixed format and HT-greenfield format transmissions can be generated using a transmitter consisting of
the following blocks:

a) **Scrambler** scrambles the data to reduce the probability of long sequences of 0s or 1s; see 20.3.11.3.

b) **Encoder parser**, if BCC encoding is to be used, demultiplexes the scrambled bits among $N_{ES}$
(number of BCC encoders for the Data field) BCC encoders, in a round robin manner.

c) **FEC encoders** encode the data to enable error correction. An FEC encoder may include a binary
convolutional encoder followed by a puncturing device, or it may include an LDPC encoder.

d) **Stream parser** divides the outputs of the encoders into blocks that are sent to different interleaver
and mapping devices. The sequence of the bits sent to an interleaver is called a spatial stream.

e) **Interleaver** interleaves the bits of each spatial stream (changes order of bits) to prevent long
sequences of adjacent noisy bits from entering the BCC decoder. Interleaving is applied only when
BCC encoding is used.

f) **Constellation mapper** maps the sequence of bits in each spatial stream to constellation points
(complex numbers).

g) **STBC** encoder spreads constellation points from $N_{SS}$ spatial streams into $N_{STS}$ space-time streams
using a space-time block code. STBC is used only when $N_{SS} < N_{STS}$; see 20.3.11.9.2.
h) **Spatial mapper** maps space-time streams to transmit chains. This may include one of the following:

1) **Direct mapping**: Constellation points from each space-time stream are mapped directly onto the transmit chains (one-to-one mapping).

2) **Spatial expansion**: Vectors of constellation points from all the space-time streams are expanded via matrix multiplication to produce the input to all the transmit chains.

3) **Beamforming**: Similar to spatial expansion, each vector of constellation points from all the space-time streams is multiplied by a matrix of steering vectors to produce the input to the transmit chains.

i) **Inverse discrete Fourier transform (IDFT)** converts a block of constellation points to a time domain block.

j) **Cyclic shift (CSD) insertion** is where the insertion of the cyclic shifts prevents unintentional beamforming. CSD insertion may occur before or after the IDFT. There are three cyclic shift types as follows:

1) A cyclic shift specified per transmitter chain with the values defined in Table 20-9 (a possible implementation is shown in Figure 20-2).

2) A cyclic shift specified per space-time stream with the values defined in Table 20-10 (a possible implementation is shown in Figure 20-3).

3) A cyclic shift $M_{CSD}(k)$ that may be applied as a part of the spatial mapper; see 20.3.11.11.2.

k) **GI insertion** prepends to the symbol a circular extension of itself.

l) **Windowing** optionally smooths the edges of each symbol to increase spectral decay.

Figure 20-2 and Figure 20-3 show example transmitter block diagrams. In particular, Figure 20-2 shows the transmitter blocks used to generate the HT-SIG of the HT-mixed format PPDU. These transmitter blocks are also used to generate the non-HT portion of the HT-mixed format PPDU, except that the BCC encoder and interleaver are not used when generating the L-STF and L-LTFs. Figure 20-3 shows the transmitter blocks used to generate the Data field of the HT-mixed format and HT-greenfield format PPDU. A subset of these transmitter blocks consisting of the constellation mapper and CSD blocks, as well as the blocks to the right of, and including, the spatial mapping block, are also used to generate the HT-STF, HT-GF-STF, and HT-LTFs. The HT-greenfield format SIGNAL field is generated using the transmitter blocks shown in Figure 20-2, augmented by additional CSD and spatial mapping blocks.

### 20.3.4 Overview of the PPDU encoding process

The encoding process is composed of the steps described below. The following overview is intended to facilitate an understanding of the details of the convergence procedure:

a) Determine the number of transmit chains, $N_{TX}$, from the N_TX field of the TXVECTOR. Produce the PLCP preamble training fields for each of the $N_{TX}$ transmit chains based on the FORMAT, NUM_EXTEN_SS, CH_BANDWIDTH, and MCS parameters of the TXVECTOR. The format and relative placement of the PLCP preamble training fields vary depending on the frame format being used, as indicated by these parameters. Apply cyclic shifts. Determine spatial mapping to be used for HT-STF and HT-LTFs in HT-mixed format frame and HT-GF-STF and HT-LTFs in HT-greenfield format frame from the EXPANSION_MAT parameter of the TXVECTOR. Refer to 20.3.9 for details.

b) Construct the PLCP preamble SIGNAL fields from the appropriate fields of the TXVECTOR by adding tail bits, applying convolutional coding, formatting into one or more OFDM symbols, applying cyclic shifts, applying spatial processing, calculating an inverse Fourier transform for each OFDM symbol and transmit chain, and prepending a cyclic prefix or GI to each OFDM symbol in each transmit chain. The number and placement of the PLCP preamble SIGNAL fields depend on the frame format being used. Refer to 20.3.9.3.5, 20.3.9.4.3, and 20.3.9.5.4.
Figure 20-2—Transmitter block diagram 1

NOTES
— There might be 1 or 2 FEC encoders when BCC encoding is used.
— The stream parser might have 1, 2, 3 or 4 outputs.
— When LDPC encoding is used, the interleavers are not used.
— When STBC is used, the STBC block has more outputs than inputs.
— When spatial mapping is used, there might be more transmit chains than space time streams.
— The number of inputs to the spatial mapper might be 1, 2, 3, or 4.

Figure 20-3—Transmitter block diagram 2
c) Concatenate the PLCP preamble training and SIGNAL fields for each transmit chain one field after another, in the appropriate order, as described in 20.3.2 and 20.3.7.

d) Use the MCS and CH_BANDWIDTH parameters of the TXVECTOR to determine the number of data bits per OFDM symbol \( N_{DBPS} \), the coding rate \( R \), the number of coded bits in each OFDM subcarrier \( N_{BPSC} \), and the number of coded bits per OFDM symbol \( N_{CBPS} \). Determine the number of encoding streams \( N_{ES} \) from the MCS, CH_BANDWIDTH, and FEC_CODING parameters of the TXVECTOR. Refer to 20.3.11.4 for details.

e) Append the PSDU to the SERVICE field (see 20.3.11.2). If BCC encoding is to be used, as indicated by the FEC_CODING parameter of the TXVECTOR, tail bits are appended to the PSDU. If a single BCC encoder is used (i.e., when the value of \( N_{ES} \) is 1), the bit string is extended by 6 zero bits. If two BCC encoders are used (i.e., when the value of \( N_{ES} \) is 2), the bit string is extended by 12 zero bits. The number of symbols, \( N_{SYM} \), is calculated according to Equation (20-32), and if necessary, the bit string is further extended with zero bits so that the resulting length is a multiple of \( N_{SYM} \times N_{DBPS} \), as described in 20.3.11. If LDPC encoding is to be used, as indicated by the FEC_CODING parameter of the TXVECTOR, the resulting bit string is padded, if needed, by repeating coded bits rather than using zero bits, as given in the encoding procedure of 20.3.11.7.5. The number of resulting symbols is given by Equation (20-41), and the number of repeated coded bits used for padding is given by Equation (20-42). The resulting bit string constitutes the DATA part of the packet.

f) Initiate the scrambler with a pseudorandom nonzero seed, generate a scrambling sequence, and exclusive-OR (XOR) it with the string of data bits, as described in 18.3.5.5.

g) If BCC encoding is to be used, replace the scrambled zero bits that served as tail bits (6 bits if the value of \( N_{ES} \) is 1, or 12 bits if the value of \( N_{ES} \) is 2) following the data with the same number of nonscrambled zero bits, as described in 18.3.5.3. (These bits return the convolutional encoder to the zero state.)

h) If BCC encoding is to be used and the value of \( N_{ES} \) is 2, divide the scrambled data bits between two BCC encoders by sending alternating bits to the two different encoders, as described in 20.3.11.5.

i) If BCC encoding is to be used, encode the extended, scrambled data string with a rate 1/2 convolutional encoder (see 18.3.5.6). Omit (puncture) some of the encoder output string (chosen according to puncturing pattern) to reach the desired coding rate, \( R \). Refer to 20.3.11.6 for details. If LDPC encoding is to be used, encode the scrambled data stream according to 20.3.11.7.5.

j) Parse the coded bit stream that results from the BCC encoding or LDPC encoding into \( N_{SS} \) spatial streams, where the value of \( N_{SS} \) is determined from the MCS parameter of the TXVECTOR. See 20.3.11.8.2 for details.

k) Divide each of the \( N_{SS} \) encoded and parsed spatial streams of bits into groups of \( N_{CBPSS}(i) \) bits. If BCC encoding is to be used, within each spatial stream and group, perform an interleaving (reordering) of the bits according to a rule corresponding to \( N_{BPSCS}(i) \), where \( i \) is the index of the spatial stream. Refer to 20.3.6 for details.

l) For each of the \( N_{SS} \) encoded, parsed, and interleaved spatial streams, divide the resulting coded and interleaved data string into groups of \( N_{BPSCS}(i) \) bits, where \( i \) is the index of the spatial stream. For each of the bit groups, convert the bit group into a complex number according to the modulation encoding tables. Refer to 18.3.5.8 for details.

m) Divide the complex number string for each of the resulting \( N_{SS} \) spatial streams into groups of \( N_{SD} \) complex numbers, where the value of \( N_{SD} \) is determined from the CH_OFFSET parameter of
TXVECTOR and the CH_BANDWIDTH parameter of TXVECTOR. Each such group is associated with one OFDM symbol in one spatial stream. In each group, the complex numbers are indexed 0 to \(N_{SD} - 1\), and these indices have an associated one-to-one correspondence with subcarrier indices via the mapping function \(M'(k)\) as described in 20.3.11.11, 20.3.11.11.3, 20.3.11.11.4, 20.3.11.11.5, and 20.3.11.12.

n) If STBC is to be applied, as indicated by the STBC parameter in the TXVECTOR, operate on the complex number associated with each data subcarrier in sequential pairs of OFDM symbols as described in 20.3.11.9.2 to generate \(N_{STS}\) OFDM symbols for every \(N_{SS}\) OFDM symbols associated with the \(N_{SS}\) spatial streams. If STBC is not to be used, the number of space-time streams is the same as the number of spatial streams, and the sequences of OFDM symbols in each space-time stream are composed of the sequences of OFDM symbols in the corresponding spatial stream. In each group of \(N_{SD}\) resulting complex numbers in each space-time stream, the complex numbers indexed 0 to \(N_{SD} - 1\) are mapped onto OFDM subcarriers via the mapping function \(M'(k)\) as described in 20.3.11.11, 20.3.11.11.3, 20.3.11.11.4, 20.3.11.11.5, and 20.3.11.12.

o) Determine whether 20 MHz or 40 MHz operation is to be used from the CH_BANDWIDTH parameter of the TXVECTOR. Specifically, when CH_BANDWIDTH is HT_CBW20 or NON_HT_CBW20, 20 MHz operation is to be used. When CH_BANDWIDTH is HT_CBW40 or NON_HT_CBW40, 40 MHz operation is to be used. For 20 MHz operation (with the exception of non-HT formats), insert four subcarriers as pilots into positions –21, –7, 7, and 21. The total number of the subcarriers, \(N_{ST}\), is 56. For 40 MHz operation (with the exception of MCS 32 and non-HT duplicate format), insert six subcarriers as pilots into positions –53, –25, –11, 11, 25, and 53, resulting in a total of \(N_{ST} = 114\) subcarriers. See 20.3.11.11.5 for pilot locations when using MCS 32 and 20.3.11.12 for pilot locations when using non-HT duplicate format. The pilots are modulated using a pseudorandom cover sequence. Refer to 20.3.11.10 for details. For 40 MHz operation, apply a +90 degree phase shift to the complex value in each OFDM subcarrier with an index greater than 0, as described in 20.3.11.11.4, 20.3.11.11.5, and 20.3.11.12.

p) Map each of the complex numbers in each of the \(N_{ST}\) subcarriers in each of the OFDM symbols in each of the \(N_{STS}\) space-time streams to the \(N_{TX}\) transmit chain inputs. For direct-mapped operation, \(N_{TX} = N_{STS}\), and there is a one-to-one correspondence between space-time streams and transmit chains. In this case, the OFDM symbols associated with each space-time stream are also associated with the corresponding transmit chain. Otherwise, a spatial mapping matrix associated with each OFDM subcarrier, as indicated by the EXPANSION_MAT parameter of the TXVECTOR, is used to perform a linear transformation on the vector of \(N_{STS}\) complex numbers associated with each subcarrier in each OFDM symbol. This spatial mapping matrix maps the vector of \(N_{STS}\) complex numbers in each subcarrier into a vector of \(N_{TX}\) complex numbers in each subcarrier. The sequence of \(N_{ST}\) complex numbers associated with each transmit chain (where each of the \(N_{ST}\) complex numbers is taken from the same position in the \(N_{TX}\) vector of complex numbers across the \(N_{ST}\) subcarriers associated with an OFDM symbol) constitutes an OFDM symbol associated with the corresponding transmit chain. For details, see 20.3.11.11. Spatial mapping matrices may include cyclic shifts, as described in 20.3.11.11.2.

q) If the CH_BANDWIDTH and CH_OFFSET parameters of the TXVECTOR indicate that upper or lower 20 MHz are to be used in 40 MHz, move the complex numbers associated with subcarriers –28 to 28 in each transmit chain to carriers 4 to 60 in the upper channel or –60 to –4 in the lower channel. Note that this shifts the signal in frequency from the center of the 40 MHz channel to +10 MHz or –10 MHz offset from the center of the 40 MHz channel. The complex numbers in the other subcarriers are set to 0.
r) For each group of $N_{ST}$ subcarriers and each of the $N_{TX}$ transmit chains, convert the subcarriers to
time domain using IDFT. Prepend to the Fourier-transformed waveform a circular extension of
itself, thus forming a GI, and truncate the resulting periodic waveform to a single OFDM symbol
length by applying time domain windowing. Determine the length of the GI according to the
GI_TYPE parameter of the TXVECTOR. Refer to 20.3.11.11 and 20.3.11.12 for details. When
beamforming is not used, it is sometimes possible to implement the cyclic shifts in the time domain.
s) Append the OFDM symbols associated with each transmit chain one after another, starting after the
final field of the PLCP preamble. Refer to 20.3.2 and 20.3.7 for details.
t) Up-convert the resulting complex baseband waveform associated with each transmit chain to an RF
signal according to the center frequency of the desired channel and transmit. Refer to 20.3.7 for
details. The transmit chains are connected to antenna elements according to ANTENNA_SET of the
TXVECTOR if ASEL is applied.

20.3.5 Modulation and coding scheme (MCS)

The MCS is a value that determines the modulation, coding, and number of spatial channels. It is a compact
representation that is carried in the HT-SIG. Rate-dependent parameters for the full set of MCSs are shown
in Table 20-30 through Table 20-44 (in 20.6). These tables give rate-dependent parameters for MCSs with
indices 0 to 76. MCSs with indices 0 to 7 and 32 have a single spatial stream; MCSs with indices 8 to 31
have multiple spatial streams using equal modulation (EQM) on all the streams; MCSs with indices 33 to 76
have multiple spatial streams using unequal modulation (UEQM) on the spatial streams. MCS indices 77 to
127 are reserved.

Table 20-30 through Table 20-33 show rate-dependent parameters for EQM MCSs for one, two, three, and
four streams for 20 MHz operation. Table 20-34 through Table 20-37 show rate-dependent parameters for
EQM MCSs in one, two, three, and four streams for 40 MHz operation. The same EQM MCSs are used for
20 MHz and 40 MHz operation. Table 20-38 shows rate-dependent parameters for the 40 MHz, 6 Mb/s
MCS 32 format.

The remaining tables, Table 20-39 to Table 20-44, show rate-dependent parameters for the MCSs with
UEQM of the spatial streams for use with $N_{SS} > 1$, including,

- Transmit beamforming
- STBC modes for which two spatial streams ($N_{SS}=2$) are encoded into three space-time streams
  ($N_{STS}=3$) and three spatial streams ($N_{SS}=3$) are encoded into four space-time streams ($N_{STS}=4$).
  These STBC mode cases are specified in Table 20-18.

UEQM MCSs are detailed in the following tables:

- Table 20-39 through Table 20-41 are for 20 MHz operation.
- Table 20-42 through Table 20-44 are for 40 MHz operation.

MCS 0 to 15 are mandatory in 20 MHz with 800 ns GI at an AP. MCS 0 to 7 are mandatory in 20 MHz with
800 ns GI at all STAs. All other MCSs and modes are optional, specifically including transmit and receive
support of 400 ns GI, operation in 40 MHz, and support of MCSs with indices 16 to 76.
### 20.3.6 Timing-related parameters

Table 20-6 defines the timing-related parameters.

20.3.7 Mathematical description of signals

For the description of the convention on mathematical description of signals, see 18.3.2.5.

In the case of either a 20 MHz non-HT format (TXVECTOR parameter FORMAT equal to NON_HT, MODULATION parameter equal to one of {DSSS-OFDM, ERP-OFDM, OFDM}) transmission or a 20 MHz HT format (TXVECTOR parameter FORMAT equal to HT_MF or HT_GF, CH_BANDWIDTH equal to HT_CBW_20) transmission, the channel is divided into 64 subcarriers. In the 20 MHz non-HT format, the signal is transmitted on subcarriers –26 to –1 and 1 to 26, with 0 being the center (dc) carrier. In the 20 MHz HT format, the signal is transmitted on subcarriers –28 to –1 and 1 to 28.

In the case of the 40 MHz HT format, a 40 MHz channel is used. The channel is divided into 128 subcarriers. The signal is transmitted on subcarriers –58 to –2 and 2 to 58.

In the case of 40 MHz HT upper format or 40 MHz HT lower format, the upper or lower 20 MHz is divided into 64 subcarriers. The signal is transmitted on subcarriers –60 to –4 in the case of a 40 MHz HT lower format transmission and on subcarriers 4 to 60 in the case of a 40 MHz HT upper format transmission.

In the case of the MCS 32 and non-HT duplicate formats, the same data are transmitted over two adjacent 20 MHz channels. In this case, the 40 MHz channel is divided into 128 subcarriers, and the data are transmitted on subcarriers –58 to –6 and 6 to 58.

The transmitted signal is described in complex base band signal notation. The actual transmitted signal is related to the complex baseband signal by the relation shown in Equation (20-1).

\[ r_{RF}(t) = \text{Re}\{r(t)\exp(j2\pi f_c t)\} \]  \hspace{1cm} (20-1)

where

- \text{Re}\{\cdot\} represents the real part of a complex variable
- \(f_c\) is the center frequency of the carrier

The transmitted RF signal is derived by modulating the complex baseband signal, which consists of several fields. The timing boundaries for the various fields are shown in Figure 20-4.

![Figure 20-4—Timing boundaries for PPDU fields](image)

The time offset, \(t_{Field}\), determines the starting time of the corresponding field.

In HT-mixed format, the signal transmitted on transmit chain \(i_{TX}\) shall be as shown in Equation (20-2).
\( r_{PPDU}^{(TX)}(t) = r_{L-STF}^{(TX)}(t) + r_{L-LTF}^{(TX)}(t - t_{L-LTF}) \)

\[ + r_{L-SIG}^{(TX)}(t - t_{L-SIG}) + r_{HT-SIG}^{(TX)}(t - t_{HT-SIG}) + r_{HT-STF}^{(TX)}(t - t_{HT-STF}) \]

\[ + \sum_{N_{LTF}}^{N_{LTF}} r_{HT-LTF}^{(TX)}(t - t_{HT-LTF} - (i_{LTF} - 1)T_{HT-LTF}) + r_{HT-DATA}^{(TX)}(t - t_{HT-DATA}) \]

where

\[ t_{L-LTF} = T_{L-STF} \]
\[ t_{L-SIG} = t_{L-LTF} + T_{L-LTF} \]
\[ t_{HT-SIG} = t_{L-SIG} + T_{L-SIG} \]
\[ t_{HT-STF} = t_{HT-SIG} + T_{HT-SIG} \]
\[ t_{HT-LTF} = t_{HT-STF} + T_{HT-STF} \]
\[ t_{HT-DATA} = t_{HT-LTF} + N_{LTF} \cdot T_{HT-LTF} \]

In the case of HT-greenfield format, the transmitted signal on transmit chain \( i_{TX} \) shall be as shown in Equation (20-3).

\[ r_{PPDU}^{(TX)}(t) = r_{HT-GF-STF}^{(TX)}(t) + r_{HT-LTF1}^{(TX)}(t - t_{HT-LTF1}) \]

\[ + r_{HT-SIG}^{(TX)}(t - t_{HT-SIG}) \]

\[ + \sum_{N_{LTF}}^{N_{LTF}} r_{HT-LTF}^{(TX)}(t - t_{HT-LTF} - (i_{LTF} - 2)T_{HT-LTF}) \]

\[ + r_{HT-DATA}^{(TX)}(t - t_{HT-DATA}) \]

where

\[ t_{HT-LTF1} = T_{HT-GF-STF} \]
\[ t_{HT-SIG} = t_{HT-LTF1} + T_{HT-LTF1} \]
\[ t_{HT-LTFs} = t_{HT-SIG} + T_{HT-SIG} \]
\[ t_{HT-DATA} = t_{HT-LTFs} + (N_{LTF} - 1) \cdot T_{HT-LTFs} \]

Each baseband waveform, \( r_{Field}^{(TX)}(t) \), is defined via the discrete Fourier transform (DFT) per OFDM symbol as shown in Equation (20-4).

\[ r_{Field}^{(TX)}(t) = \frac{1}{\sqrt{N_{TX}}} \sum_{n=0}^{N_{TX}} Y_{k}^{(TX)} \exp(j2\pi k\Delta_f t) \]
This general representation holds for all fields. A suggested definition of the windowing function, \( w_{\text{Field}}(t) \), is given in 18.3.2.5. The frequency-domain symbols \( X_k(f_{TX}) \) represent the output of any spatial processing in subcarrier \( k \) for transmit chain \( f_{TX} \) required for the field.

The function \( \Upsilon_k \) is used to represent a rotation of the upper tones in a 40 MHz channel as shown in Equation (20-5) and Equation (20-6).

\[
\Upsilon_k = \begin{cases} 
1, & k \leq 0, \text{ in a 40 MHz channel} \\
 j, & k > 0, \text{ in a 40 MHz channel}
\end{cases} \tag{20-5}
\]

\[
\Upsilon_k = 1, \text{ in a 20 MHz channel} \tag{20-6}
\]

The \( \frac{1}{\sqrt{N_{\text{Field}}}} \) scale factor in Equation (20-4) ensures that the total power of the time domain signal as summed over all transmit chains is either 1 or lower than 1 when required. Table 20-8 summarizes the various values of \( N_{\text{Field}}^{\text{Tone}} \).

\begin{table}[h]
\centering
\begin{tabular}{|c|c|c|}
\hline
Field & \( N_{\text{Field}}^{\text{Tone}} \) see NOTE 1 & \\
\hline
 & 20 MHz & 40 MHz \\
L-STF & 12 & 24 \\
HT-GF-STF & 12 & 24 \\
L-LTF & 52 & 104 \\
L-SIG & 52 & 104 \\
HT-SIG & 52/56, see NOTE 2 & 104/114, see NOTE 2 \\
HT-STF & 12 & 24 \\
HT-LTF & 56 & 114 \\
HT-Data & 56 & 114 \\
MCS 32, see NOTE 3 & — & 104 \\
\hline
\end{tabular}
\caption{Value of tone scaling factor \( N_{\text{Field}}^{\text{Tone}} \)}
\end{table}

**NOTE 1**—The numbers in the table refer only to the value of \( N_{\text{Field}}^{\text{Tone}} \) as it appears in Equation (20-4) and in subsequent specification of various fields. This value might be different from the actual number of tones being transmitted.

**NOTE 2**—The values 56 and 114 are for HT-greenfield format; the values 52 and 104 are for HT-mixed format.

**NOTE 3**—This is the Data field in an MCS 32 format PPDU.

### 20.3.8 Transmission in the upper/lower 20 MHz of a 40 MHz channel

When transmitting in the upper/lower 20 MHz portion of a 40 MHz channel, the mathematical definition of transmission shall follow that of a 20 MHz channel with \( f_c \) in Equation (20-1) replaced by \( f_c \pm 10 \text{ MHz} \).
This rule applies to 20 MHz HT transmission in the upper/lower 20 MHz of a 40 MHz channel (TXVECTOR primitive CH_BANDWIDTH equal to HT_CBW20 and CH_OFFSET primitive equal to CH_OFF_20U or CH_OFF_20L) and to 20 MHz non-HT transmission in the upper/lower 20 MHz of a 40 MHz channel (TXVECTOR primitive CH_BANDWIDTH equal to NON_HT_CBW20 and CH_OFFSET primitive equal to CH_OFF_20U or CH_OFF_20L).

20.3.9 HT preamble

20.3.9.1 Introduction

The HT preambles are defined in HT-mixed format and in HT-greenfield format to carry the required information to operate in a system with multiple transmit and multiple receive antennas.

In the HT-mixed format, to ensure compatibility with non-HT STAs, specific non-HT fields are defined so that they can be received by non-HT STAs compliant with Clause 18 or Clause 19 followed by the fields specific to HT STAs.

In the HT-greenfield format, all of the non-HT fields are omitted. The specific HT fields used are as follows:

- One HT-GF-STF for automatic gain control convergence, timing acquisition, and coarse frequency acquisition,
- One or several HT-LTFs, provided as a way for the receiver to estimate the channel between each spatial mapper input and receive chain. The first HT-LTFs (HT-DLTFs) are necessary for demodulation of the HT-Data portion of the PPDU and are followed, for sounding packets only, by optional HT-LTFs (HT-ELTFs) to sound extra spatial dimensions of the MIMO channel,
- HT-SIG, which provides all the information required to interpret the HT packet format.

In the case of multiple transmit chains, the HT preambles use cyclic shift techniques to prevent unintentional beamforming.

20.3.9.2 HT-mixed format preamble

In HT-mixed format frames, the preamble has fields that support compatibility with Clause 18 and Clause 19 STAs and fields that support HT operation. The non-HT portion of the HT-mixed format preamble enables detection of the PPDU and acquisition of carrier frequency and timing by both HT STAs and STAs that are compliant with Clause 18 or Clause 19. The non-HT portion of the HT-mixed format preamble contains the SIGNAL field (L-SIG) defined in Clause 18 and is thus decodable by STAs compliant with Clause 18 and Clause 19 as well as HT STAs.

The HT portion of the HT-mixed format preamble enables estimation of the MIMO channel to support demodulation of the data portion of the frame by HT STAs. The HT portion of the HT-mixed format preamble also contains the HT-SIG field that supports HT operation.

20.3.9.3 Non-HT portion of the HT-mixed format preamble

20.3.9.3.1 Introduction

The transmission of the non-HT training fields and the L-SIG as part of an HT-mixed format packet is described in 20.3.9.3.2 through 20.3.9.3.5.

20.3.9.3.2 Cyclic shift definition

The cyclic shift values defined in this subclause apply to the non-HT fields in the HT-mixed format preamble and the HT-SIG in the HT-mixed format preamble.
Cyclic shifts are used to prevent unintentional beamforming when the same signal or scalar multiples of one signal are transmitted through different spatial streams or transmit chains. A cyclic shift of duration $T_{CS}$ on a signal $s(t)$ on interval $0 \leq t \leq T$ is defined as follows, where $T$ is defined as $T_{DFT}$ as referenced in Table 20-6.

With $T_{CS} \leq 0$, replace $s(t)$ with $s(t - T_{CS})$ when $0 \leq t < T + T_{CS}$ and with $s(t - T_{CS} - T)$ when $T + T_{CS} \leq t \leq T$. The cyclic-shifted signal is defined as shown in Equation (20-7).

$$s_{CS}(t;T_{CS})|_{T_{CS} < 0} = \begin{cases} s(t - T_{CS}) & 0 \leq t < T + T_{CS} \\ s(t - T_{CS} - T) & T + T_{CS} \leq t \leq T \end{cases}$$  \hspace{1cm} (20-7)

The cyclic shift is applied to each OFDM symbol in the packet separately. Table 20-9 specifies the values for the cyclic shifts that are applied in the L-STF (in an HT-mixed format packet), the L-LTF, and L-SIG. It also applies to the HT-SIG in an HT-mixed format packet.

### Table 20-9—Cyclic shift for non-HT portion of packet

<table>
<thead>

</tbody>
</table>

With more than four transmit chains, each cyclic shift on the additional transmit chains shall be between −200 ns and 0 ns inclusive.

#### 20.3.9.3.3 L-STF definition

The L-STF is identical to the Clause 18 short training symbol. The non-HT short training OFDM symbol in the 20 MHz channel width is shown in Equation (20-8).

$$S_{20,26} = \sqrt{\frac{1}{2}} \{ 0, 0, 1+j, 0, 0, 0, 1+j, 0, 0, 0, 0, 1+j, 0, 0, 0, 1+j, 0, 0, 0, 1+j, 0, 0, 0, 1+j, 0, 0, 0, 1+j, 0, 0 \}$$  \hspace{1cm} (20-8)

The normalization factor $\sqrt{1/2}$ is the QPSK normalization.

The non-HT short training OFDM symbol in a 40 MHz channel width is given by Equation (20-9), after rotating the tones in the upper subchannel (subcarriers 6–58) by +90° (see Equation (20-10)).

where
i

TX
T CS

represents the cyclic shift for transmit chain i TX and takes values from Table 20-9

ϒk

is defined in Equation (20-5) and Equation (20-6)

The L-STF has a period of 0.8 µs. The entire STF includes ten such periods, with a total duration of T L-STF
= 8 µs.

20.3.9.3.4 L-LTF definition
The non-HT long training OFDM symbol is identical to the Clause 18 long training OFDM symbol. In the
20 MHz channel width, the long training OFDM symbol is given by Equation (20-11).
L – 26,26 = { 1, 1, – 1, – 1, 1, 1, – 1, 1, – 1, 1, 1, 1, 1, 1, 1, – 1, – 1, 1, 1, – 1, 1, – 1, 1, 1, 1, 1, 0,
1, – 1, – 1, 1, 1, –1, 1, – 1, 1, – 1, – 1, –1, – 1, – 1, 1, 1, – 1, – 1, 1, – 1, 1, – 1, 1, 1, 1, 1 }

(20-11)

The non-HT long training OFDM symbol in a 40 MHz channel width is given by Equation (20-12), after
rotating the tones in the upper subchannel (subcarriers 6–58) by +90º (see Equation (20-13)).
L – 58,58 = { 1, 1, – 1, – 1, 1, 1, – 1, 1, – 1, 1, 1, 1, 1, 1, 1, – 1, – 1, 1, 1, – 1, 1, – 1, 1, 1, 1, 1, 0,
1, – 1, – 1, 1, 1 , – 1, 1, – 1 , 1, – 1, – 1 , – 1 , – 1 , – 1 , 1, 1 , – 1, – 1, 1 , – 1, 1, – 1 , 1, 1, 1 , 1 , 0, 0 , 0 , 0 , 0,
0, 0 , 0 , 0 , 0, 0 , 1 , 1, – 1 , – 1 , 1, 1 , – 1, 1, – 1 , 1 , 1, 1 , 1 , 1 , 1, – 1, – 1, 1 , 1 , – 1 , 1 , – 1 , 1, 1 , 1 , 1 , 0,
1, – 1, – 1, 1, 1 , – 1, 1, – 1 , 1, – 1, – 1 , – 1 , – 1 , – 1 , 1, 1 , – 1, – 1, 1 , – 1, 1, – 1 , 1, 1, 1 , 1 }

(20-12)

The subcarriers at ± 32 in 40 MHz, which are the dc subcarriers for the non-HT 20 MHz transmission, are
both nulled in the L-LTF. Such an arrangement allows proper synchronization of a 20 MHz non-HT STA.
The L-LTF waveform shall be as shown in Equation (20-13).

Copyright © 2012 IEEE. All rights reserved.


\( Y_k \) is defined in Equation (20-5) and Equation (20-6)

The entire LTF includes two 3.2 µs IDFT/DFT periods and an additional 1.6 µs double GI. The entire LTF is modulated with the L-LTF waveform.

### 20.3.9.3.5 L-SIG definition

The L-SIG is used to communicate rate and length information. The structure of the L-SIG is shown in Figure 20-5.

![Figure 20-5—L-SIG structure](image)

The value in the Rate field is obtained from the L_DATARATE field of the TXVECTOR. The value in the Length field is obtained from the L_LENGTH field of the TXVECTOR. The Length field is transmitted LSB first.

The reserved bit shall be set to 0.

The parity field has the even parity of bits 0–16.

The L-SIG shall be encoded, interleaved and mapped, and it shall have pilots inserted following the steps described in 18.3.5.6, 18.3.5.7, and 18.3.5.9. The stream of 48 complex numbers generated by the steps described in 18.3.5.7 is denoted by \( d_k, k = 0 \ldots 47 \). The time domain waveform of the L-SIG in 20 MHz transmission shall be as given by Equation (20-14).

\[
\begin{align*}
    r_{L-SIG}^{(tx)}(t) &= \frac{1}{\sqrt{N_{TX} \cdot N_{L-SIG}}} \sum_{k=-26}^{26} (D_k + p_0 P_k) \exp(j2\pi k\Delta_F(t - T_{GI} - \frac{T_{CS}}{2}))
\end{align*}
\]  

(20-14)

In a 40 MHz transmission the time domain waveform of the L-SIG shall be as given by Equation (20-15).

\[
\begin{align*}
    r_{L-SIG}^{(tx)}(t) &= \frac{1}{\sqrt{N_{TX} \cdot N_{L-SIG}}} \sum_{k=-26}^{26} (D_k + p_0 P_k) \\
    &\cdot (\exp(j2\pi(k-32)\Delta_F(t - T_{GI} - \frac{T_{CS}}{2})) + j \exp(j2\pi(k+32)\Delta_F(t - T_{GI} - \frac{T_{CS}}{2})))
\end{align*}
\]  

(20-15)

where

\[
D_k = \begin{cases} 
0, & k = 0, \pm 7, \pm 21 \\
\overline{d_{M(k)}}, & \text{otherwise}
\end{cases}
\]
is defined in 18.3.5.10

$p_0$ is the first pilot value in the sequence defined in 18.3.5.10

$N^\text{tone}\_\text{SIG}_L$ has the value given in Table 20-8

$T^\text{TX}\_CS$ represents the cyclic shift for transmit chain $i_{TX}$ and is defined by Table 20-9 for HT-mixed format PPDUs

NOTE—$D_k$ exists for $-N_{NSR} \leq k \leq N_{NSR}$ and takes the values from $d_k$ that exists for $0 \leq k \leq N_{NSD} - 1$. $M'(k)$ is a “reverse” function of the function $M(k)$ defined in 18.3.5.10.

**20.3.9.4 HT portion of HT-mixed format preamble**

**20.3.9.4.1 Introduction**

When an HT-mixed format preamble is transmitted, the HT preamble consists of the HT-STF, the HT-LTFs, and the HT-SIG.

**20.3.9.4.2 Cyclic shift definition**

The cyclic shift values defined in this subclause apply to the HT-STF and HT-LTFs of the HT-mixed format preamble. The cyclic shift values defined in 20.3.9.3.2 apply to the HT-SIG in an HT-mixed format preamble.

Throughout the HT portion of an HT-mixed format preamble, cyclic shift is applied to prevent beamforming when similar signals are transmitted in different space-time streams. The same cyclic shift is applied to these streams during the transmission of the data portion of the frame. The values of the cyclic shifts to be used during the HT portion of the HT-mixed format preamble (with the exception of the HT_SIG) and the data portion of the frame are specified in Table 20-10.

</tbody>
</table>

NOTE 1—Integer fields are transmitted in unsigned binary format, LSB first.
NOTE 2—A value of 0 in the HT Length field indicates a PPDU that does not include a data field, i.e., NDP. NDP transmissions are used for sounding purposes only (see 9.31.2). The packet ends after the last HT-LTF or the HT-SIG.
The structure of the HT-SIG\textsubscript{1} and HT-SIG\textsubscript{2} fields is defined in Figure 20-6.

![Figure 20-6—Format of HT-SIG\textsubscript{1} and HT-SIG\textsubscript{2}](image)

The HT-SIG is composed of two parts, HT-SIG\textsubscript{1} and HT-SIG\textsubscript{2}, each containing 24 bits, as shown in Figure 20-6. All the fields in the HT-SIG are transmitted LSB first, and HT-SIG\textsubscript{1} is transmitted before HT-SIG\textsubscript{2}.

The HT-SIG parts shall be encoded at R = 1/2, interleaved, and mapped to a BPSK constellation, and they have pilots inserted following the steps described in 18.3.5.6, 18.3.5.7, 18.3.5.8, and 18.3.5.9, respectively. The BPSK constellation is rotated by 90° relative to the L-SIG in order to accommodate detection of the start of the HT-SIG. The stream of 96 complex numbers generated by these steps is divided into two groups of 48 complex numbers: \( d_{k,n} \), \( 0 \leq k \leq 47 \), \( n = 0, 1 \). The time domain waveform for the HT-SIG in an HT-mixed format packet in a 20 MHz transmission shall be as shown in Equation (20-16).

\[
r_{\text{HT-SIG}}(t) = \frac{1}{\sqrt{N_{TX} \cdot N_{\text{HT-SIG}}}} \cdot \sum_{n=0}^{1} w_{T_{\text{SYM}}} (t-nT_{\text{SYM}}) \\
\cdot \sum_{k=-26}^{26} (jD_{k,n} + p_{n+1}P_k) \exp(j2\pi k\Delta_f(t-nT_{\text{SYM}}-T_{GI}-T_{CS}))
\]  

Equation (20-16)
For a 40 MHz transmission, the time domain waveform shall be as shown in Equation (20-17).

\[
\begin{align*}
\tau_{HT-SIG,tx}(t) &= \frac{1}{\sqrt{N_{TX} \cdot N_{HT-SIG}^{\text{Tone}}}} \sum_{n=0}^{26} w_{n}^{\text{SYM}}(t-nT_{SYM}) \\
&\cdot \sum_{k=-26}^{\infty} (jD_{k,n} + p_{n}^{k} + \frac{1}{2}P_{k}) (\exp(j2\pi(k-32)\Delta_{F}(t-nT_{SYM}-T_{GI} - \frac{T_{CS}^{tx}}{2}))) \\
&+ j \exp(j2\pi(k+32)\Delta_{F}(t-nT_{SYM}-T_{GI} - \frac{T_{CS}^{tx}}{2})))
\end{align*}
\]

(20-17)

where

\[
D_{k,n} = \begin{cases} 
0, k = 0, \pm 7, \pm 21 \\
\frac{d'}{M'(k),n'}, \text{otherwise}
\end{cases}
\]

\(M'(k)\) is defined in 20.3.9.3

\(P_{k}\) and \(p_{n}\) are defined in 18.3.5.10

\(N_{HT-SIG}^{\text{Tone}}\) has the value given in Table 20-8

\(T_{CS}^{tx}\) represents the cyclic shift for transmit chain \(t_{tx}\) and is defined by Table 20-9 for HT-mixed format PPDUs.

NOTE—This definition results in a quadrature binary phase shift keying (QBPSK) modulation in which the constellation of the data tones is rotated by 90° relative to the L-SIG in HT-mixed format PPDUs and relative to the first HT-LTF in HT-greenfield format PPDUs (see Figure 20-7). In HT-mixed format PPDUs, the HT-SIG is transmitted with the same number of subcarriers and the same cyclic shifts as the preceding non-HT portion of the preamble. This is done to accommodate the estimation of channel parameters needed to robustly demodulate and decode the information contained in the HT-SIG.

Figure 20-7—Data tone constellations in an HT-mixed format PPDU

20.3.9.4.4 CRC calculation for HT-SIG

The CRC protects bits 0–33 of the HT-SIG (bits 0–23 of HT-SIG\textsubscript{1} and bits 0–9 of HT-SIG\textsubscript{2}). The value of the CRC field shall be the ones complement of
where

\[ M(D) = m_0 D^{33} + m_1 D^{32} + \ldots + m_{32} D + m_{33} \]

is the HT-SIG represented as a polynomial

where

- \( m_0 \) is bit 0 of HT-SIG1
- \( m_{33} \) is bit 9 of HT-SIG2

\[ I(D) = \sum_{i=26}^{33} D^i \]

are initialization values that are added modulo 2 to the first 8 bits of HT-SIG1

\[ G(D) = D^8 + D^2 + D + 1 \]

is the CRC generating polynomial

\[ \text{crc}(D) = c_0 D^7 + c_1 D^6 + \ldots + c_6 D + c_7 \]

The CRC field is transmitted with \( c_7 \) first.

Figure 20-8 shows the operation of the CRC. First, the shift register is reset to all ones. The bits are then passed through the XOR operation at the input. When the last bit has entered, the output is generated by shifting the bits out of the shift register, \( C7 \) first, through an inverter.

As an example, if bits \( \{m_0 \ldots m_{33}\} \) are given by \( \{1 1 1 1 0 0 0 1 0 0 1 \ldots \} \), the output bits \( \{b_7 \ldots b_0\} \), where \( b_7 \) is output first, are \( \{1 0 1 0 1 0 0\} \).

### 20.3.9.4.5 HT-STF definition

The purpose of the HT-STF is to improve automatic gain control estimation in a MIMO system. The duration of the HT-STF is 4 µs. In a 20 MHz transmission, the frequency sequence used to construct the HT-STF is identical to L-STF. In a 40 MHz transmission, the HT-STF is constructed from the 20 MHz version by duplicating and frequency shifting and by rotating the upper subcarriers by 90°. The frequency sequences are shown in Equation (20-19) and Equation (20-20).

For 20 MHz:

\[ HTS_{28,28} = \sqrt{1/2} \]

\[ \{0, 0, 0, 0, 1 + j, 0, 0, 0, -1 - j, 0, 0, 0, 1 + j, 0, 0, 0, -1 - j, 0, 0, 0, -1 - j, 0, 0, 0, 1 + j, 0, 0, 0, \ldots\} \]
IEEE
Std 802.11-2012

PART 11: WIRELESS LAN MAC AND PHY SPECIFICATIONS

For 40 MHz:
HTS –58,58 = 1 ⁄ 2
{ 0, 0, 1 + j, 0, 0, 0, – 1 – j, 0, 0, 0, 1 + j, 0, 0, 0, – 1 – j, 0, 0, 0, – 1 – j, 0, 0, 0, 1 + j, 0, 0, 0,
0, 0, 0, 0, – 1 – j, 0, 0, 0, – 1 – j, 0, 0, 0, 1 + j, 0, 0, 0, 1 + j, 0, 0, 0, 1 + j, 0, 0, 0, 1 + j, 0, 0, 0, 0, 0,

ϒk

is defined in Equation (20-5) and Equation (20-6)

20.3.9.4.6 HT-LTF definition
The HT-LTF provides a means for the receiver to estimate the MIMO channel between the set of QAM
mapper outputs (or, if STBC is applied, the STBC encoder outputs) and the receive chains. If the transmitter
is providing training for exactly the space-time streams (spatial mapper inputs) used for the transmission of
the PSDU, the number of training symbols, N LTF , is equal to the number of space-time streams, N STS ,
except that for three space-time streams, four training symbols are required. If the transmitter is providing
training for more space-time streams (spatial mapper inputs) than the number used for the transmission of
the PSDU, the number of training symbols is greater than the number of space-time streams. This latter case
happens in a sounding PPDU.
The HT-LTF portion has one or two parts. The first part consists of one, two, or four HT-LTFs that are
necessary for demodulation of the HT-Data portion of the PPDU. These HT-LTFs are referred to as
HT-DLTFs. The optional second part consists of zero, one, two, or four HT-LTFs that may be used to sound
extra spatial dimensions of the MIMO channel that are not utilized by the HT-Data portion of the PPDU.
These HT-LTFs are referred to as HT-ELTFs. If a receiver has not advertised its ability to receive HT-ELTFs,
it shall either issue a PHY-RXEND.indicate(UnsupportedRate) primitive upon reception of a frame that
includes HT-ELTFs or decode that frame. (When an HT packet includes one or more HT-ELTFs, it is
optional for a receiver that has not advertised its capability to receive HT-ELTFs to decode the data portion
of the PPDU.)
The number of HT-DLTFs is denoted N HTDLTF . The number of HT-ELTFs is denoted N HTELTF . The total
number of HT-LTFs is shown in Equation (20-22).
N HTLTF = N HTDLTF + N HTELTF

shall not exceed 5. Table 20-12 shows the determination of the number of space-time streams from the MCS and STBC fields in the HT-SIG. Table 20-13 shows the number of HT-DLTFs as a function of the number of space-time streams \(N_{STS}\). Table 20-14 shows the number of HT-ELTFs as a function of the number of extension spatial streams \(N_{ESS}\). \(N_{STS}\) plus \(N_{ESS}\) is less than or equal to 4. In the case where \(N_{STS}\) equals 3, \(N_{ESS}\) cannot exceed one; if \(N_{ESS}\) equals one in this case then \(N_{LTF}\) equals 5.

The HT-LTF sequence shown in Equation (20-23) is transmitted in the case of 20 MHz operation.
NOTE—This sequence is an extension of the L-LTF where the four extra subcarriers are filled with +1 for negative frequencies and –1 for positive frequencies.

In 40 MHz transmissions, including MCS 32 format frames, the sequence to be transmitted is shown in Equation (20-24).

\[
HTLT_{28,28} = \{1, 1, 1, -1, -1, 1, 1, -1, 1, 1, 1, 1, -1, -1, 1, -1, 1, -1, 1, 1, 1, 1, 0, \\
-1, -1, -1, 1, 1, -1, 1, -1, -1, 1, -1, 1, 1, -1, 1, 1, 1, 1, -1, -1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1\} \tag{20-23}
\]

NOTE—This sequence is also constructed by extending the L-LTF in the following way: first, the L-LTF is duplicated and shifted as explained in 20.3.9.3.4 for the non-HT duplicate format; then the missing subcarriers [–32, –5, –4, –3, –2, 2, 3, 4, 5, 32] are filled with the values [1, –1, –1, –1, –1, 1, –1, 1, 1, 1, 1], respectively.

This sequence, occupying 114 tones, is used even if the data portion is transmitted with MCS 32 format, which uses 104 tones.

NOTE—This sequence uses 114 tones when MCS 32 format is used to retain consistency with other 40 MHz formats and to facilitate channel estimation for beamforming and link adaptation.

In an HT-mixed format preamble, each HT-LTF consists of a single occurrence of the sequence plus a GI insertion and has a duration of 4 µs. In case of multiple space-time streams, cyclic shift is invoked as specified in Table 20-10.

The generation of HT-DLTFs is shown in Figure 20-9. The generation of HT-ELTFs is shown in Figure 20-10. In these figures, and in the following text, the following notational conventions are used:

- \([X]_{m,n}\) indicates the element in row \(m\) and column \(n\) of matrix \(X\)
- \([X]_N\) indicates a matrix consisting of the first \(N\) columns of matrix \(X\)
- \([X]_{M,N}\) indicates a matrix consisting of columns \(M\) to \(N\) of matrix \(X\)

where

\[
M \leq N
\]

\(X\) is either \(Q_k\) or \(P_{HTLT}\)

Figure 20-9—Generation of HT-DLTFs
The mapping between space-time streams and transmit chains is defined by the columns of an antenna map matrix $Q_k$ for subcarrier $k$. The first $N_{STS}$ columns define the space-time streams used for data transmission, and the next $N_{ESS}$ columns (up to $N_{TX} - N_{STS}$ columns) define the extension spatial streams. Thus, for the purpose of defining HT-LTFs, $Q_k$ is an $N_{TX} \times (N_{STS} + N_{ESS})$ dimension matrix. Columns $1 \ldots N_{STS}$ of $Q_k$ are excited by the HT-DLTFs, and columns $N_{STS} + 1 \ldots N_{STS} + N_{ESS}$ are excited by the HT-ELTFs, where $N_{STS} + N_{ESS} \leq N_{TX}$ is the total number of spatial streams being probed by the HT-LTFs.

Possible forms of $Q_k$ and other limitations on $Q_k$ are specified in 20.3.11.1.1. $P_{HTLTF}$ is defined in Equation (20-27).

The time domain representation of the waveform transmitted on transmit chain $i_{TX}$ during HT-DLTF $n$, where $1 \leq n \leq N_{HTDLTF}$, shall be as shown in Equation (20-25).

$$r_{HT-LTF}(t) = \frac{1}{\sqrt{N_{STS} \cdot N_{HT-LTF}}}w_{HT-LTF}(t) \cdot \sum_{k=-N_{SR}}^{N_{SR}} \sum_{i_{STS}=1}^{N_{STS}} [Q_k]_{i_{TX},i_{STS}}[P_{HTLTF}]_{i_{STS},n}Y_k^{HTLTF}(t) \exp(j2\pi k\Delta \mu(t - T_{GI} - \tau_{CS}^{STS}))$$

(20-25)
For the HT-ELTFs \((N_{HTDLTF} < n \leq N_{HTLTF})\), it shall be as shown in Equation (20-26).

\[
T_{HT-LTF}(t) = \frac{1}{\sqrt{N_{HTLTF} \cdot N_{ESS}}} \sum_{n=-N_{SR}}^{N_{SR}} \sum_{i_{ESS}=-1}^{1} \left( [Q_k]_{ix, -n} \cdot [P_{HTLTF}]_{i_{ESS}, -n} \cdot Y_k \cdot HTLTF_k \right) \cdot \exp(j2\pi k\Delta_f(t - T_{GI} - T_{ESS}))
\]

(20-26)

where

- \(T_{STS}^{CS}\) cyclic shift values are given in Table 20-10
- \(T_{ESS}^{CS}\) cyclic shift values are given in Table 20-10 with \(i_{ESS} = i_{STS}\)
- \(Q_k\) is defined in 20.3.11.11.2
- \(Y_k\) is defined in Equation (20-5) and Equation (20-6)
- \(P_{HTLTF}\) the HT-LTF mapping matrix, is given by Equation (20-27)

\[
P_{HTLTF} = \begin{bmatrix}
1 & -1 & 1 & 1 \\
1 & 1 & -1 & 1 \\
1 & 1 & 1 & -1 \\
-1 & 1 & 1 & 1
\end{bmatrix}
\]

(20-27)

20.3.9.5 HT-greenfield format preamble

20.3.9.5.1 General

For HT-greenfield operation, compatibility with Clause 18 and Clause 19 STAs is not required. Therefore, the portions of the preamble that are compatible with Clause 18 and Clause 19 STAs are not included. The result is a shorter and more efficient PLCP frame format that includes a STF, LTF(s), and an HT-SIG.

20.3.9.5.2 Cyclic shift definition for HT-greenfield format preamble

Throughout the HT-greenfield format preamble, cyclic shift is applied to prevent beamforming when similar signals are transmitted on different spatial streams. The same cyclic shift is applied to these streams during the transmission of the data portion of the frame. The values of the cyclic shift to be used during the HT-greenfield format preamble, as well as the data portion of the HT-greenfield format frame, are specified in Table 20-10.

20.3.9.5.3 HT-GF-STF definition

The HT-GF-STF is placed at the beginning of an HT-greenfield format frame. The time domain waveform for the HT-GF-STF on transmit chain \(i_{TX}\) shall be as shown in Equation (20-28).
\[ r_{HT-GF-STF}^{(i_{TX})}(t) = \frac{1}{\sqrt{N_{STS} \cdot N_{HT-GF-STF}}} \sum_{n} w_{HT-GF-STF}(t) \cdot \sum_{k=\text{NSTS}-N_{SF}}^{N_{SF}} \sum_{i_{STS}=1}^{N_{STS}} [Q_{k}]_{i_{TX},i_{STS}} \cdot [P_{HTLTF}]_{i_{STS},1} \cdot \gamma_{k} \cdot \exp(j2\pi k\Delta_f(t - T_{CS}^{i_{STS}})) \]  

(20-28)

where

- \( T_{CS} \) represents the cyclic shift for the space-time stream \( i_{STS} \) and takes values from Table 20-10
- \( Q_{k} \) is defined in 20.3.11.11.2
- \( P_{HTLTF} \) is defined in Equation (20-27)
- \( S_{k} \) is defined in non-HT-STF (L-STF), Equation (20-8) for 20 MHz operation and Equation (20-9) for 40 MHz operation
- \( \gamma_{k} \) is defined in Equation (20-5) and Equation (20-6)

The waveform defined by Equation (20-28) has a period of 0.8 µs, and the HT-GF-STF includes ten such periods, with a total duration of \( T_{HT-GF-STF} = 8 \) µs.

### 20.3.9.5.4 HT-greenfield format HT-SIG

The content and format of the HT-SIG of an HT-greenfield format frame is identical to the HT-SIG in an HT-mixed format frame, as described in 20.3.9.4.3. The placement of the HT-SIG in an HT-greenfield format frame is shown in Figure 20-1. In HT-greenfield format frames, the HT-SIG is transmitted with the same cyclic shifts and the same spatial mapping as the preceding portions of the preamble. This use of the same cyclic shifts and spatial mapping is done to accommodate the estimation of channel parameters needed to robustly demodulate and decode the information contained in the HT-SIG.

The time domain waveform for the HT-SIG on transmit chain \( i_{TX} \) with 20 MHz operation shall be as shown in Equation (20-29).

\[ r_{HT-SIG}^{(i_{TX})}(t) = \frac{1}{\sqrt{N_{STS} \cdot N_{HT-SIG}}} \sum_{n=0}^{1} w_{SYM}(t - nT_{SYM}) \cdot \sum_{k=-26}^{26} \sum_{i_{STS}=1}^{N_{STS}} [Q_{k}]_{i_{TX},i_{STS}} \cdot [P_{HTLTF}]_{i_{STS},1} \cdot (jD_{k,n} + P_{n}P_{k}) \cdot \exp(j2\pi k\Delta_f(t - nT_{SYM} - T_{GI} - T_{CS}^{i_{STS}})) \]  

(20-29)

where

- \( P_{k} \) and \( p_{n} \) are defined in 18.3.5.10
- \( D_{k,n} \) is defined in 20.3.9.4.3
- \( T_{CS}^{i_{STS}} \) represents the cyclic shift for space-time stream \( i_{STS} \) and takes values from Table 20-10
- \( Q_{k} \) is defined in 20.3.11.11.2
\( P_{HTLTF} \) is defined in Equation (20-27)

The time domain waveform for the HT-SIG on transmit chain \( i_{TX} \) with 40 MHz operation shall be as shown in Equation (20-30).

\[
\begin{align*}
&\mathcal{r}_{HT-SIG}^{i_{TX}}(t) = \frac{1}{\sqrt{N_{STS} \cdot N_{HT-SIG}}} \sum_{n = 0}^{1} w_{SYM}(t - n T_{SYM}) \\
&\cdot \sum_{k = -26}^{26} \sum_{i_{STS} = 1}^{N_{STS}} [P_{HTLTF}]_{i_{TX}i_{STS}} (jD_{k,n} + p_{n} P_{k}) \\
&\cdot [Q_{k - 32}]_{i_{TX}i_{STS}} \exp(j2\pi(k - 32)\Delta \tau (t - n T_{SYM} - T_{GI} - T_{CS}^{jSTS})) \\
&\quad + j[Q_{k + 32}]_{i_{TX}i_{STS}} \exp(j2\pi(k + 32)\Delta \tau (t - n T_{SYM} - T_{GI} - T_{CS}^{jSTS}))
\end{align*}
\]

where

- \( p_{n} \) and \( P_{k} \) are defined in 18.3.5.10
- \( D_{k,n} \) is defined in 20.3.9.4.3
- \( T_{CS}^{jSTS} \) represents the cyclic shift for space-time stream \( i_{STS} \) and takes values from Table 20-10
- \( Q_{k} \) is defined in 20.3.11.11.2
- \( P_{HTLTF} \) is defined in Equation (20-27)

### 20.3.9.5.5 HT-greenfield format LTF

The format of the LTF portion of the preamble in an HT-greenfield format frame is similar to that of the HT-LTF in an HT-mixed format frame, as described in 20.3.9.4.6, with the difference that the first HT-LTF (HT-LTF1) is twice as long (8 \( \mu \)s) as the other HT-LTFs. The time domain waveform for the long training symbol on transmit chain \( i_{TX} \) for the first HT-LTF in an HT-greenfield format frame shall be as shown in Equation (20-31).

\[
\begin{align*}
&\mathcal{r}_{HT-LTF}^{1,i_{TX}}(t) = \frac{1}{\sqrt{N_{STS} \cdot N_{HT-LTF}}} w_{HT-LTF1}(t) \\
&\cdot \sum_{k = -N_{SR}}^{N_{SR}} \sum_{i_{STS} = 1}^{N_{STS}} [Q_{k}]_{i_{TX}i_{STS}} [P_{HTLTF}]_{i_{TX}i_{STS}} \cdot \exp(j2\pi k \Delta \tau (t - T_{GI2} - T_{CS}^{jSTS}))
\end{align*}
\]

where

- \( T_{CS}^{jSTS} \) represents the cyclic shift for space-time stream \( i_{STS} \) and takes values from Table 20-10
- \( Q_{k} \) is defined in 20.3.11.11.2
- \( P_{HTLTF} \) is defined in Equation (20-27)
The first HT-LTF (HT-LTF1) consists of two periods of the long training symbol, preceded by a double-length (1.6 μs) cyclic prefix. The placement of the first and subsequent HT-LTFs in an HT-greenfield format frame is shown in Figure 20-1.

20.3.10 Transmission of NON_HT format PPDUs with more than one antenna

When an HT device transmits a NON_HT format PDU with the MODULATION parameter equal to OFDM or ERP-OFDM using more than one transmit chain, it shall apply the cyclic shifts defined in Table 20-9 to the transmission in each chain.

20.3.11 Data field

20.3.11.1 General

When BCC encoding is used, the Data field consists of the 16-bit SERVICE field, the PSDU, either six or twelve tail bits, depending on whether one or two encoding streams are represented, and pad bits. When LDPC encoding is used, the Data field consists of the 16-bit SERVICE field and the PSDU, processed by the procedure in 20.3.11.7.5.

The number of OFDM symbols in the data field when BCC encoding is used is computed as shown in Equation (20-32).

\[ N_{SYM} = m_{STBC} \left\lfloor \frac{8 \cdot \text{length} + 16 + 6 \cdot N_{ES}}{m_{STBC} \cdot N_{DBPS}} \right\rfloor \]  

(20-32)

where

- \( m_{STBC} \) is 2 if STBC is used and 1 otherwise (making sure that the number of symbols is even when STBC is used)
- \( \text{length} \) is the value of the HT Length field in the HT-SIG field defined in Table 20-11
- \( N_{DBPS} \) takes the values defined in Table 20-30 through Table 20-44
- \( \left\lfloor x \right\rfloor \) denotes the smallest integer greater than or equal to \( x \)

The number of “zero” pad bits is thus \( N_{SYM} \times N_{DBPS} - 8 \times \text{length} - 16 - 6 \times N_{ES} \). The number of symbols in the data field when LDPC encoding is used is described in 20.3.11.7.

For LDPC encoding, the number of encoded data bits, \( N_{\text{avbits}} \), is given by Equation (20-39); the number of OFDM symbols, \( N_{SYM} \), is given by Equation (20-41); and the number of repeated encoded bits for padding, \( N_{\text{rep}} \), is given by Equation (20-42), in 20.3.11.7.5.

20.3.11.2 SERVICE field

The SERVICE field is used for scrambler initialization. The SERVICE field is composed of 16 bits, all set to 0 before scrambling. In non-HT PPDUs, the SERVICE field is the same as in 18.3.5.2. In HT PPDUs, the SERVICE field is composed of 16 zero bits, scrambled by the scrambler, as defined in 20.3.11.3.

20.3.11.3 Scrambler

The data field shall be scrambled by the scrambler defined in 18.3.5.5 and initialized with a pseudorandom nonzero seed.
20.3.11.4 Coding

The Data field shall be encoded using either the BCC defined in 18.3.5.6 or the LDPC code defined in 20.3.11.7. The encoder is selected by the FEC coding field in the HT-SIG, as described in 20.3.9.4.3. A single FEC encoder is always used when LDPC coding is used. When the BCC FEC encoder is used, a single encoder is used, except that two encoders are used when the selected MCS has a PHY rate greater than 300 Mb/s (see 20.6). To determine whether to use one or two BCC FEC encoders, the rate is calculated based on the use of an 800 ns GI. The operation of the BCC FEC is described in 20.3.11.6. The operation of the LDPC coder is described in 20.3.11.7.

Support for the reception of BCC-encoded Data field frames is mandatory.

20.3.11.5 Encoder parsing operation for two BCC FEC encoders

If two BCC encoders are used, the scrambled data bits are divided between the encoders by sending alternating bits to different encoders. Bit with index $i$ sent to the encoder $j$, denoted $x_i^{(j)}$, is shown in Equation (20-33).

$$x_i^{(j)} = b_{N_{ES}, i+j} ; \quad 0 \leq j \leq N_{ES} - 1$$

(20-33)

Following the parsing operation, 6 scrambled “zero” bits following the end of the message bits in each BCC input sequence are replaced by unscrambled “zero” bits, as described in 18.3.5.3.

The replaced bits are shown in Equation (20-34).

$$x_i^{(j)} : \quad 0 \leq j \leq N_{ES} - 1 ; \quad \frac{\text{length} \cdot 8 + 16}{N_{ES}} \leq i \leq \frac{\text{length} \cdot 8 + 16}{N_{ES}} + 5$$

(20-34)

20.3.11.6 Binary convolutional coding and puncturing

When BCC encoding is used, the encoder parser output sequences $\{x_i^0\}$, and $\{x_i^1\}$ where applicable, are each encoded by the rate 1/2 convolutional encoder defined in 18.3.5.6. After encoding, the encoded data shall be punctured by the method defined in 18.3.5.7 to achieve the rate selected by the MCS.

If rate 5/6 coding is selected, the puncturing scheme is defined in Figure 20-11.

20.3.11.7 LDPC codes

20.3.11.7.1 Introduction

HT LDPC codes are described in 20.3.11.7.2 through 20.3.11.7.6. These codes are optionally used in the HT system as a high-performance error correcting code instead of the convolutional code (20.3.11.6). The LDPC encoder shall use the rate-dependent parameters in Table 20-30 through Table 20-44, with the exception of the $N_{ES}$ parameter.

Support for LDPC codes is optional.

20.3.11.7.2 LDPC coding rates and codeword block lengths

The supported coding rates, information block lengths, and codeword block lengths are described in Table 20-15.
Figure 20-11—Puncturing at rate 5/6

20.3.11.7.3 LDPC encoder

For each of the three available codeword block lengths, the LDPC encoder supports rate 1/2, rate 2/3, rate 3/4, and rate 5/6 encoding. The LDPC encoder is systematic, i.e., it encodes an information block, \( c = (i_0, i_1, \ldots, i_{k-1}) \), of size \( k \), into a codeword, \( c' = (c_0, c_1, \ldots, c_{n-k}) \), by adding \( n-k \) parity bits obtained so that \( H \times c^T = 0 \), where \( H \) is an \( (n-k) \times n \) parity-check matrix. The selection of the codeword block length \( n \) is achieved via the LDPC PPDU encoding process described in 20.3.11.7.5.

20.3.11.7.4 Parity-check matrices

Each of the parity-check matrices is partitioned into square subblocks (submatrices) of size \( Z \times Z \). These submatrices are either cyclic-permutations of the identity matrix or null submatrices.

The cyclic-permutation matrix \( P_i \) is obtained from the \( Z \times Z \) identity matrix by cyclically shifting the columns to the right by \( i \) elements. The matrix \( P_0 \) is the \( Z \times Z \) identity matrix. Figure 20-12 illustrates examples (for a subblock size of \( 8 \times 8 \)) of cyclic-permutation matrices \( P_i \).

\[
P_0 = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}, \quad P_1 = \begin{bmatrix} 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix}, \quad P_5 = \begin{bmatrix} 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}
\]

**Figure 20-12—Examples of cyclic-permutation matrices with \( Z=8 \)**

Table F-1 displays the “matrix prototypes” of parity-check matrices for all four coding rates at block length \( n=648 \) bits. The integer \( i \) denotes the cyclic-permutation matrix \( P_i \), as illustrated in Figure 20-12. Vacant entries of the table denote null (zero) submatrices.

Table F-2 displays the matrix prototypes of parity-check matrices for block length \( n=1296 \) bits, in the same fashion.

Table F-3 displays the matrix prototypes of parity-check matrices for block length \( n=1944 \) bits, in the same fashion.

20.3.11.7.5 LDPC PPDU encoding process

To encode an LDPC PPDU, step a) through step g) shall be performed in sequence:

a) Compute the number of available bits, \( N_{avbits} \), in the minimum number of OFDM symbols in which the Data field of the packet may fit.

\[
N_{pbd} = \text{length} \times 8 + 16 \quad (20-35)
\]

\[
N_{avbits} = N_{CBPS} \times m_{STBC} \times \left\lfloor \frac{N_{pbd}}{N_{CBPS} \times R \times m_{STBC}} \right\rfloor \quad (20-36)
\]
where

\[ m_{STBC} \] is 2 if STBC is used and 1 otherwise

\[ \text{length} \] is the value of the HT Length field in the HT-SIG field defined in Table 20-11

\[ \lceil x \rceil \] denotes the smallest integer greater than or equal to \( x \)

\( N_{\text{pld}} \) is the number of bits in the PSDU and SERVICE field

b) Compute the integer number of LDPC codewords to be transmitted, \( N_{\text{CW}} \), and the length of the codewords to be used, \( L_{\text{LDPC}} \) from Table 20-16.

c) Compute the number of shortening bits, \( N_{\text{shrt}} \), to be padded to the \( N_{\text{pld}} \) data bits before encoding, as shown in Equation (20-37).

\[
N_{\text{shrt}} = \max(0, (N_{\text{CW}} \times L_{\text{LDPC}} \times R) - N_{\text{pld}})
\]  

(20-37)

When \( N_{\text{shrt}} = 0 \), shortening is not performed. (Note that \( N_{\text{shrt}} \) is inherently restricted to be non-negative due to the codeword length and count selection of 20-16). When \( N_{\text{shrt}} > 0 \), shortening bits shall be equally distributed over all \( N_{\text{CW}} \) codewords with the first \( \text{rem}(N_{\text{shrt}} \times N_{\text{CW}}) \) codewords shortened 1 bit more than the remaining codewords. Define \( N_{\text{spcw}} = \left\lceil \frac{N_{\text{shrt}}}{N_{\text{CW}}} \right\rceil \). Then, when \( N_{\text{shrt}} > 0 \), the shortening is performed by setting information bits \( i_{k-N_{\text{spcw}}} \), \( \ldots, i_{k-1} \) to 0 in the first \( \text{rem}(N_{\text{shrt}} \times N_{\text{CW}}) \) codewords and setting information bits \( i_{k-N_{\text{spcw}}} \), \( \ldots, i_{k-1} \) to 0 in the remaining codewords. For all values of \( N_{\text{shrt}} \), encode each of the \( N_{\text{CW}} \) codewords using the LDPC encoding technique described in 20.3.11.7.2 through 20.3.11.7.4. When \( N_{\text{shrt}} > 0 \), the shortened bits shall be discarded after encoding.

d) Compute the number of bits to be punctured, \( N_{\text{punc}} \), from the codewords after encoding, as shown in Equation (20-38).

\[
N_{\text{punc}} = \max(0, (N_{\text{CW}} \times L_{\text{LDPC}}) - N_{\text{avbits}} - N_{\text{shrt}})
\]  

(20-38)
If \( (N_{\text{punc}} > 0.1 \times N_{\text{CW}} \times L_{\text{LDPC}} \times (1 - R)) \) AND \( (N_{\text{shrt}} < 1.2 \times N_{\text{punc}} \times \frac{R}{1 - R}) \) is true OR if \( (N_{\text{punc}} > 0.3 \times N_{\text{CW}} \times L_{\text{LDPC}} \times (1 - R)) \) is true, increment \( N_{\text{avbits}} \) and recompute \( N_{\text{punc}} \) by the following two equations once:

\[
N_{\text{avbits}} = N_{\text{avbits}} + N_{\text{CBPS}} \times m_{\text{STBC}} \quad (20-39)
\]

\[
N_{\text{punc}} = \max(0, (N_{\text{CW}} \times L_{\text{LDPC}}) - N_{\text{avbits}} - N_{\text{shrt}}) \quad (20-40)
\]

The punctured bits shall be equally distributed over all \( N_{\text{CW}} \) codewords with the first \( \text{rem}(N_{\text{punc}}, N_{\text{CW}}) \) codewords punctured 1 bit more than the remaining codewords. Define \( N_{\text{ppcw}} = \left\lfloor \frac{N_{\text{punc}}}{N_{\text{CW}}} \right\rfloor \). When \( N_{\text{ppcw}} > 0 \), the puncturing is performed by discarding parity bits \( p_{n-k-N_{\text{ppcw}}-1}, \ldots, p_{n-k-1} \) of the first \( \text{rem}(N_{\text{punc}}, N_{\text{CW}}) \) codewords and discarding parity bits \( (p_{n-k-N_{\text{punc}}}, \ldots, p_{n-k-1}) \) of the remaining codewords after encoding. The number of OFDM symbols to be transmitted in the PPDU is computed as shown in Equation (20-41).

\[
N_{\text{SYM}} = \frac{N_{\text{avbits}}}{N_{\text{CBPS}}} \quad (20-41)
\]

e) Compute the number of coded bits to be repeated, \( N_{\text{rep}} \), as shown in Equation (20-42).

\[
N_{\text{rep}} = \max(0, N_{\text{avbits}} - N_{\text{CW}} \times L_{\text{LDPC}} \times (1 - R) - N_{\text{pid}}) \quad (20-42)
\]

The number of coded bits to be repeated shall be equally distributed over all \( N_{\text{CW}} \) codewords with one more bit repeated for the first \( \text{rem}(N_{\text{rep}}, N_{\text{CW}}) \) codewords than for the remaining codewords.

NOTE—When puncturing occurs, the coded bits are not repeated, and vice versa.

The coded bits to be repeated for any codeword shall be copied only from that codeword itself, starting from information bit \( i_0 \) and continuing sequentially through the information bits and, when necessary, into the parity bits, until the required number of repeated bits is obtained for that codeword. Note that these repeated bits are copied from the codeword after the shortening bits have been removed. If for a codeword the required number of repeated bits are not obtained in this manner (i.e., repeating the codeword once), the procedure is repeated until the required number is achieved. These repeated bits are then concatenated to the codeword after the parity bits in their same order. This process is illustrated in Figure 20-13. In this figure, the outlined arrows indicate the encoding procedure steps, while the solid arrows indicate the direction of puncturing and padding with repeated bits.

f) For each of the \( N_{\text{CW}} \) codewords, process the data using the number of shortening bits per codeword as computed in step c) for encoding, and puncture or repeat bits per codeword as computed per step d) and step e), as illustrated in Figure 20-13.

g) Aggregate all codewords and parse as defined in 20.3.11.7.6.

20.3.11.7.6 LDPC parser

The succession of LDPC codewords that result from the encoding process of 20.3.11.7.5 shall be converted into a bitstream in sequential fashion. Within each codeword, bit \( i_0 \) is ordered first. The parsing of this encoded data stream into spatial streams shall follow exactly the parsing rules defined for the BCC encoder, as defined in 20.3.11.8.1. However, the frequency interleaver of 20.3.11.8.3 is bypassed.
20.3.11.8 Data interleaver

20.3.11.8.1 Overview

After coding and puncturing, the data bit streams at the output of the FEC encoders are rearranged into blocks of \( N_{CBPSS}(i_{SS}) \) bits, where \( i_{SS} = 1, 2, \ldots, N_{SS} \) is the spatial stream index. This operation is referred to as stream parsing and is described in 20.3.11.8.2. If BCC encoding was used, each of these blocks is then interleaved by an interleaver that is a modification of the Clause 18 interleaver.

20.3.11.8.2 Stream parser

The number of bits assigned to a single axis (real or imaginary) in a constellation point in spatial stream \( i_{SS} \) is denoted by Equation (20-43).

\[
s(i_{SS}) = \max \left\{ 1, \frac{N_{BPSCS}(i_{SS})}{2} \right\}
\]  

(20-43)

The sum of these over all streams is \( S = \sum_{i_{SS} = 1}^{N_{SS}} s(i_{SS}) \).

NOTE—If equal MCS is used for all spatial streams, this sum becomes \( N_{SS} \cdot s \), where \( s \) is the number of bits for an axis common to all streams.

Consecutive blocks of \( s(i_{SS}) \) bits are assigned to different spatial streams in a round robin fashion.

If two encoders are present, the output of each encoder is used alternately for each round robin cycle, i.e., at the beginning \( S \) bits from the output of first encoder are fed into all spatial streams, and then \( S \) bits from the output of second encoder are used, and so on.

Input \( k \) to spatial stream \( i_{SS} \) shall be \( y_{j}^{(i)} \), which is output bit \( i \) of the encoder \( j \),
where

\[ j = \left\lfloor \frac{k}{s(i_{SS})} \right\rfloor \mod N_{ES} \tag{20-44} \]

\[ i = \sum_{t=1}^{i_{SS}-1} s(t) + s(i_{SS}) \left\lfloor \frac{k}{N_{ES} \cdot s(i_{SS})} \right\rfloor + k \mod s(i_{SS}) \tag{20-45} \]

\[ 1 \leq i_{SS} \leq N_{SS} \]

\[ \lfloor x \rfloor \] is the largest integer less than or equal to \( x \)

\[ z \mod t \] is the remainder resulting from the division of integer \( z \) by integer \( t \)

For \( i_{SS} = 1 \), the first term in Equation (20-45) has a value of 0.

### 20.3.11.8.3 Frequency interleaver

MCS 32 interleaving shall be as defined in 18.3.5.7. Interleaving for all other MCSs is defined in this subclause.

The bits at the output of the stream parser are divided into blocks of \( N_{CBPSS}(i_{SS}), i_{SS} = 1, 2, \ldots N_{SS} \) bits; and if BCC encoding was used, each block shall be interleaved by an interleaver based on the Clause 18 interleaver. This interleaver, which is based on entering the data in rows and reading them out in columns, has a different number of columns and rows depending on whether a 20 MHz channel or a 40 MHz channel is used. Table 20-17 defines the interleaver parameters. If LDPC encoding was used, no frequency interleaving is performed; hence the parsed streams are immediately mapped to symbols as defined in 20.3.11.9.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>20 MHz</th>
<th>40 MHz</th>
</tr>
</thead>
<tbody>
<tr>
<td>( N_{COL} )</td>
<td>13</td>
<td>18</td>
</tr>
<tr>
<td>( N_{ROW} )</td>
<td>( 4 \times N_{BPSCS}(i_{SS}) )</td>
<td>( 6 \times N_{BPSCS}(i_{SS}) )</td>
</tr>
<tr>
<td>( N_{ROT} )</td>
<td>11</td>
<td>29</td>
</tr>
</tbody>
</table>

If more than one spatial stream exists after the operations based on the Clause 18 interleaver have been applied, a third operation called frequency rotation shall be applied to the additional spatial streams. The parameter for the frequency rotation is \( N_{ROT} \).

The interleaving is defined using three permutations. The first permutation is defined by the rule shown in Equation (20-46).

\[ i = N_{ROW}(k \mod N_{COL}) + \text{Floor}(k/N_{COL}) \quad k = 0, 1, \ldots, N_{CBPSS}(i_{SS}) - 1 \tag{20-46} \]

The second permutation is defined by the rule shown in Equation (20-47).
The value of \( s(i_{SS}) \) is determined by the number of coded bits per subcarrier as shown in Equation (20-48).

\[
s(i_{SS}) = \max(N_{BPSCS}(i_{SS})/2, 1) \tag{20-48}
\]

If more than one spatial stream exists, a frequency rotation is applied to the output of the second permutation as shown in Equation (20-49).

\[
r = \left( j - \left( (i_{SS} - 1) \times 2 \right) \right) \mod 3 + 3 \times \floor{\frac{i_{SS} - 1}{3}} \times N_{ROT} \times N_{BPSCS}(i_{SS}) \mod N_{CBPSS}(i_{SS}) ;
\]
\[
j = 0, 1, \ldots, N_{CBPSS}(i_{SS}) - 1
\tag{20-49}
\]

where

\( i_{SS} = 1, 2, \ldots, N_{SS} \) is the index of the spatial stream on which this interleaver is operating.

The deinterleaver uses the following operations to perform the inverse rotation. The index of the bit in the received block (per spatial stream) is denoted by \( r \). The first permutation reverses the third (frequency rotation) permutation of the interleaver as shown in Equation (20-50).

\[
j = \left( r + \left( (i_{SS} - 1) \times 2 \right) \right) \mod 3 + 3 \times \floor{\frac{i_{SS} - 1}{3}} \times N_{ROT} \times N_{BPSCS}(i_{SS}) \mod N_{CBPSS}(i_{SS}) ;
\]
\[
r = 0, 1, \ldots, N_{CBPSS}(i_{SS}) - 1
\tag{20-50}
\]

The second permutation reverses the second permutation in the interleaver as shown in Equation (20-51).

\[
i = s(i_{SS}) \times \floor{j/s(i_{SS})} + (j + \floor{N_{COL} \times j/N_{CBPSS}(i_{SS})}) \mod s(i_{SS}) ;
\]
\[
j = 0, 1, \ldots, N_{CBPSS}(i_{SS}) - 1
\tag{20-51}
\]

where \( s(i_{SS}) \) is defined in Equation (20-48).

The third permutation reverses the first permutation of the interleaver as shown in Equation (20-52).

\[
k = N_{COL} \times i - (N_{CBPSS}(i_{SS}) - 1) \times \floor{i/N_{ROW}} ;
\]
\[
i = 0, 1, \ldots, N_{CBPSS}(i_{SS}) - 1
\tag{20-52}
\]

20.3.11.9 Constellation mapping

20.3.11.9.1 General

The mapping between bits at the output of the interleaver and complex constellation points for BPSK, QPSK, 16-QAM, and 64-QAM follows the rules defined in 18.3.5.8.

The streams of complex numbers are denoted as shown in Equation (20-53).

\[
d_{k,l,n} \quad 0 \leq k \leq N_{SD} - 1 ; 1 \leq l \leq N_{SS} ; 0 \leq n \leq N_{SYM} - 1
\tag{20-53}
20.3.11.9.2 Space-time block coding (STBC)

This subclause defines a set of optional robust transmission formats that are applicable only when \( N_{STS} \) is greater than \( N_{SS} \). In this case, \( N_{SS} \) spatial streams are mapped to \( N_{STS} \) space-time streams, which are mapped to \( N_{TX} \) transmit chains. These formats are based on STBC. When the use of STBC is indicated in the STBC field of the HT-SIG, a symbol operation shall occur between the constellation mapper and the spatial mapper (see Figure 20-3) as defined in this subclause.

If STBC is applied, the stream of complex numbers, \( d_{k,i,n} ; k = 0 \ldots N_{SD} - 1; i = 1 \ldots N_{SS}; n = 0 \ldots N_{SYM} - 1 \), generated by the constellation mapper, is the input of the STBC encoder, which produces as output the stream of complex numbers \( \tilde{d}_{k,i,n} ; k = 0 \ldots N_{SD} - 1; i = 1 \ldots N_{STS}; n = 0 \ldots N_{SYM} - 1 \). For given values of \( k \) and \( i \), STBC processing operates on the complex modulation symbols in sequential pairs of OFDM symbols so that the value of \( \tilde{d}_{k,i,2m} \) depends on \( d_{k,i,2m} \) and \( d_{k,i,2m+1} \), and \( \tilde{d}_{k,i,2m+1} \) also depends on \( d_{k,i,2m} \) and \( d_{k,i,2m+1} \), as defined in Table 20-18.

20.3.11.11 OFDM modulation

20.3.11.11.1 General

The time domain signal is composed from the stream of complex numbers as shown in Equation (20-56)

$$\tilde{d}_{k,l,n}, 0 \leq k \leq N_{SD} - 1; 1 \leq l \leq N_{STS}; 0 \leq n \leq N_{SYM} - 1$$  \hspace{1cm} (20-56)

and from the pilot signals. For a 40 MHz transmission, the upper subcarriers are rotated 90° relative to the lower subcarriers.

20.3.11.11.2 Spatial mapping

The transmitter may choose to rotate and/or scale the constellation mapper output vector (or the space-time block coder output, if applicable). This rotation and/or scaling is useful in the following cases:

- When there are more transmit chains than space-time streams, $N_{STS} < N_{TX}$
- As part of (an optional) sounding packet
- As part of (an optional) calibration procedure
- When the packet is transmitted using one of the (optional) beamforming techniques

If the data to be transmitted on subcarrier $k$ on space-time stream $i_{STS}$ are $X_{k}^{(i_{STS})}$, the transmitted data on the transmit chain $i_{TX}$ shall be as shown in Equation (20-57).

$$r_{Field}^{(i_{TX})} = \frac{1}{\sqrt{N_{STS} \cdot N_{Field}^{Tone}}} w_{Field}(t) \sum_{k=-N_{SR}}^{N_{SR}} \sum_{i_{STS}=-N_{STS}}^{N_{STS}} [Q_{k}]_{i_{TX},i_{STS}} X_{k}^{(i_{STS})} \exp(j2\pi k \Delta_F(t - T_{CS}^{i_{STS}}))$$  \hspace{1cm} (20-57)

where

- $[Q_{k}]_{i_{TX},i_{STS}}$ is the element in row $i_{TX}$ and column $i_{STS}$ in a matrix $Q_{k}$ with $N_{TX}$ rows and $N_{STS}$ columns;
- $Q_{k}$ may be frequency dependent
- $Field$ is any field, as defined in 20.3.7, excluding L-STF, L-LTF, L-SIG, and HT-SIG in HT_MF format PPDU

Below are examples of spatial mapping matrices that might be used. There exist many other alternatives; implementation is not restricted to the spatial mapping matrices shown. The examples are:

a) Direct mapping: $Q_{k}$ is a diagonal matrix of unit magnitude complex values that takes one of two forms:
   1) $Q_{k} = I$, the identity matrix
   2) A CSD matrix in which the diagonal elements represent cyclic shifts in the time domain:
      $$[Q_{k}]_{i,i} = \exp(-j2\pi k \Delta_F \tau_{CS}^{i}),$$
      where $\tau_{CS}^{i}, i = 1, ..., N_{TX}$ represents the CSD applied.

b) Indirect mapping: $Q_{k}$ may be the product of a CSD matrix and a unitary matrix such as the Hadamard matrix or the Fourier matrix.

c) Spatial expansion: $Q_{k}$ is the product of a CSD matrix and a square matrix formed of orthogonal columns. As an illustration:
1) The spatial expansion may be performed by duplicating some of the $N_{STS}$ streams to form the $N_{TX}$ streams, with each stream being scaled by the normalization factor $\sqrt{N_{STS}/N_{TX}}$. The spatial expansion may be performed by using, for instance, one of the following matrices, denoted $D$, left-multiplied by a CSD matrix, denoted $M_{CSD}(k)$, and/or possibly multiplied by any unitary matrix. The resulting spatial mapping matrix is then $Q_k = M_{CSD}(k) \cdot D$, where $D$ may take on one of the following values:

   i) $N_{TX}=2, N_{STS}=1, D = \frac{1}{\sqrt{2}} \begin{bmatrix} 1 & 1 \end{bmatrix}^T$
   
   ii) $N_{TX}=3, N_{STS}=1, D = \frac{1}{\sqrt{3}} \begin{bmatrix} 1 & 1 & 1 \end{bmatrix}^T$
   
   iii) $N_{TX}=4, N_{STS}=1, D = \frac{1}{2} \begin{bmatrix} 1 & 1 & 1 \end{bmatrix}^T$
   
   iv) $N_{TX}=3, N_{STS}=2, D = \frac{\sqrt{2}}{\sqrt{3}} \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \\
   1 & 0 & 0 \end{bmatrix}$
   
   v) $N_{TX}=4, N_{STS}=2, D = \frac{1}{\sqrt{2}} \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \\
   1 & 0 & 0 \end{bmatrix}$
   
   vi) $N_{TX}=4, N_{STS}=3, D = \frac{2\sqrt{3}}{2} \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\
   1 & 0 & 0 & 0 \end{bmatrix}$

2) Different spatial expansion over subcarriers should be used in HT-mixed format only and with the smoothing bit equal to 0:

   i) $N_{TX}=2, N_{STS}=1, [Q_k]_{N_{STS}} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \\ 0 & 0 \end{bmatrix}^T$ or $[Q_k]_{N_{STS}} = \begin{bmatrix} 0 & 1 \\ 1 & 0 \\ 0 & 0 \end{bmatrix}^T$
   
   ii) $N_{TX}=3, N_{STS}=2, [Q_k]_{N_{STS}} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{bmatrix}$ or $[Q_k]_{N_{STS}} = \begin{bmatrix} 0 & 0 \\ 1 & 0 \\ 0 & 1 \\ 0 & 0 \end{bmatrix}$
   
   iii) $N_{TX}=4, N_{STS}=2, [Q_k]_{N_{STS}} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \end{bmatrix}$ or $[Q_k]_{N_{STS}} = \begin{bmatrix} 0 & 0 \\ 1 & 0 \\ 0 & 1 \\ 0 & 0 \\ 0 & 0 \end{bmatrix}$
   
   iv) $N_{TX}=4, N_{STS}=3, [Q_k]_{N_{STS}} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{bmatrix}$ or $[Q_k]_{N_{STS}} = \begin{bmatrix} 0 & 0 \\ 1 & 0 \\ 0 & 1 \\ 0 & 0 \\ 0 & 0 \end{bmatrix}$

   d) **Beamforming steering matrix:** $Q_k$ is any matrix that improves the reception in the receiver based on some knowledge of the channel between the transmitter and the receiver. With transmit
beamforming with explicit feedback, the steering matrix $Q_k$ is determined using either $H_{\text{eff}}$ for CSI feedback or $V_k$ for noncompressed and compressed matrices feedback from the STA to which the beamformed packet is addressed.

When there are fewer space-time streams than transmit chains, the first $N_{\text{STS}}$ columns of the matrices above that are square might be used.

The same matrix $Q_k$ shall be applied to subcarrier $k$ during all parts of the packet in HT-greenfield format and all parts of the packet following and including the HT-STF field in an HT-mixed format packet. This operation is transparent to the receiver.

If 95% of the sum of the energy from all impulse responses of the time domain channels between all space-time streams and all transmit chain inputs, induced by the CSD added according to Table 20-10 and the frequency-dependence in the matrix $Q_k$, is contained within 800 ns, the smoothing bit should be set to 1. Otherwise, it shall be set to 0.

The CSD of Table 20-10 shall be applied at the input of the spatial mapper.

For the identity matrix direct mapping, the smoothing bit should be set to 1.

If no spatial mapping is applied, the matrix $Q_k$ is equal to the identity matrix and $N_{\text{STS}} = N_{\text{TX}}$.

Sounding PPDUs using spatial expansion shall use an orthonormal column matrix $Q_k$. When the number of rows and columns is equal, the orthonormal column matrix becomes a unitary matrix.

### 20.3.11.11.3 Transmission in 20 MHz HT format

For 20 MHz HT transmissions, the signal from transmit chain $i_{\text{TX}}, 1 \leq i_{\text{TX}} \leq N_{\text{TX}}$ shall be as shown in Equation (20-58).

$$
\begin{align*}
\frac{i_{\text{TX}}}{i_{\text{HT-DATA}}(t)} &= \frac{1}{\sqrt{N_{\text{STS}} \cdot N_{\text{TONET}}}^{\text{HT-DATA}}} \sum_{n=0}^{N_{\text{SYM}}-1} w_{\text{SYM}}(t - nT_{\text{SYM}}) \\
&\quad \cdot \sum_{k=-N_{\text{SR}}}^{N_{\text{SR}}} \sum_{i_{\text{STS}}=1}^{N_{\text{STS}}} (Q_{ki_{\text{TX}},i_{\text{STS}}} \tilde{D}_{k,i_{\text{STS}}} n + p_{n} z P_{i_{\text{TX}},i_{\text{STS}},n}) \\
&\quad \cdot \exp(j2\pi k\Delta f(t - nT_{\text{SYM}} - T_{GL} - T_{CS}^{i_{\text{STS}}}))
\end{align*}
$$

(20-58)

where

- $z$ is 3 in an HT-mixed format packet and 2 in an HT-greenfield format packet
- $p_{n}$ is defined in 18.3.5.10

$$
\tilde{D}_{k,i_{\text{STS}},n} = \begin{cases} 
0, & k = 0, \pm 7, \pm 21 \\
\tilde{d}_{M(k),i_{\text{STS}},n}, & \text{otherwise}
\end{cases}
$$
is defined in Equation (20-54)

20.3.11.11.4 Transmission in 40 MHz HT format

For 40 MHz HT transmissions, the signal from transmit chain $i_{TX}$ shall be as shown in Equation (20-59).

$$
M'(k) = \begin{cases} 
  & k + 28, -28 \leq k \leq -22 \\
  & k + 27, -20 \leq k \leq -8 \\
  & k + 26, -6 \leq k \leq -1 \\
  & k + 25, 1 \leq k \leq 6 \\
  & k + 24, 8 \leq k \leq 20 \\
  & k + 23, 22 \leq k \leq 28 
\end{cases}
$$

$P^k_{(i_{STP}n)}$ is defined in Equation (20-54)

where $z$ is defined in 18.3.5.10

$$
P^k_{(i_{STP}n)} = \begin{cases} 
  & 0, k = 0, \pm 1, \pm 11, \pm 25, \pm 53 \\
  & \tilde{d}_{M'(k), i_{STP}n}^* \text{ otherwise} 
\end{cases}
$$

NOTE—The 90° rotation that is applied to the upper part of the 40 MHz channel is applied in the same way to the HT-STF, HT-LTF, and HT-SIG. The rotation applies to both pilots and the data in the upper part of the 40 MHz channel.
20.3.11.11.5 Transmission in MCS 32 format

MCS 32 format provides the lowest transmission rate in 40 MHz. It is used only for one spatial stream and only with BPSK modulation and rate 1/2 coding.

In the MCS 32 format, the signal shall be as shown in Equation (20-60).

\[
i_{HT-DATA}^{tx}(t) = \frac{1}{\sqrt{N_{TX-Duplicate}^{HT}}} \sum_{n=0}^{N_{SYM}-1} w_{SYM}^{HT}(t-nT_{SYM}) \cdot \sum_{k=-N_{SR}}^{N_{SR}} (D_{k,n} + p_n \cdot z^k)([Q_{k-32}]_{TX} \cdot 1) \exp(j2\pi(k-32)\Delta F(t-nT_{SYM}-T_{GI})) \]

\[+ j[Q_{k+32}]_{TX} \cdot 1 \exp(j2\pi(k+32)\Delta F(t-nT_{SYM}-T_{GI})))
\]

where
- \(z\) is defined in 20.3.11.11.3
- \(P_k\) and \(p_n\) are defined in 18.3.5.10
- \(D_{k,n}\) is defined in 20.3.9.4.3
- \(N_{SR}\) has the value defined for non-HT 20 MHz transmission
- \([Q_{k}]_{TX} \cdot 1\) is an element from a vector of length \(N_{TX}\), which may be frequency dependent
- \(N_{TX-Duplicate}^{HT}\) is defined in Table 20-8

The rules of spatial expansion CSD limitation, as specified in 20.3.11.11.2, shall apply to \([Q_{k}]_{TX} \cdot 1\).

20.3.11.11.6 Transmission with a short GI

Short GI is used in the data field of the packet when the Short GI field in the HT-SIG is equal to 1. When it is used, the same formula for the formation of the signal shall be used as in 20.3.11.11.3, 20.3.11.11.4, and 20.3.11.11.5, with \(T_{GI}\) replaced by \(T_{GIS}\) and \(T_{SYM}\) replaced by \(T_{SYMS}\).

NOTE—Short GI is not used in HT-greenfield format with one spatial stream, in which case the HT-SIG is immediately followed by data. It is very difficult to parse the HT-SIG in time to demodulate these data with the correct GI length if the GI length is not known in advance.

20.3.11.12 Non-HT duplicate transmission

Non-HT duplicate transmission is used to transmit to Clause 18 STAs, Clause 19 STAs, and Clause 20 STAs that may be present in either the upper or lower halves of the 40 MHz channel. The L-STF, L-LTF, and L-SIG shall be transmitted in the same way as in the HT 40 MHz transmission. The HT-SIG, HT-STF, and HT-LTF are not transmitted. Data transmission shall be as defined in Equation (20-61).
Beamforming

20.3.12.1 General

Beamforming is a technique in which the beamformer utilizes the knowledge of the MIMO channel to generate a steering matrix $Q_k$ that improves reception in the beamformee.

The equivalent complex baseband MIMO channel model is one in which, when a vector $x_k = [x_1, x_2, ... x_{N_{TX}}]^T$ is transmitted in subcarrier $k$, the received vector $y_k = [y_1, y_2, ... y_{N_{RX}}]^T$ is modeled as shown in Equation (20-62).

$$y_k = H_k x_k + n$$  \hspace{1cm} (20-62)

where

- $H_k$ is channel matrix of dimensions $N_{RX} \times N_{TX}$
- $n$ is white (spatially and temporally) Gaussian noise as illustrated in Figure 20-14

When beamforming is used, the beamformer replaces $x_k$, which in this case has $N_{STS} \leq N_{TX}$ elements, with $Q_k x_k$, where $Q_k$ has $N_{TX}$ rows and $N_{STS}$ columns, so that the received vector is as shown in Equation (20-63).

$$y_k = H_k Q_k x_k + n$$  \hspace{1cm} (20-63)

The beamforming steering matrix that is computed (or updated) from a new channel measurement replaces the existing $Q_k$ for the next beamformed data transmission. There are several methods of beamforming, differing in the way the beamformer acquires the knowledge of the channel matrices $H_k$ and on whether the beamformer generates $Q_k$ or the beamformee provides feedback information for the beamformer to generate $Q_k$. 

\[
\begin{align*}
    r_{\text{LEG-DUP}}^T(t) &= \frac{1}{\sqrt{N_{\text{HT-Duplicate}}}} \sum_{n=0}^{N_{\text{SYM}}-1} w_n(t-nT_{\text{SYM}}) \\
    &\quad \cdot \sum_{k=-26}^{26} (D_{k,n} + p_{n+1}P_k)(\exp(j2\pi(k-32)\Delta_F(t-nT_{\text{SYM}}-T_{\text{GI}}-T_{\text{CS}}))) \\
    &\quad + j\exp(j2\pi(k+32)\Delta_F(t-nT_{\text{SYM}}-T_{\text{GI}}-T_{\text{CS}}))) \\
\end{align*}
\]

where

- $P_k$ and $p_n$ are defined in 18.3.5.10
- $D_{k,n}$ is defined in 20.3.9.4.3
- $T_{\text{CS}}^{\text{TX}}$ represents the cyclic shift of the transmit chain $i_{\text{TX}}$ and is defined in Table 20-9
- $N_{\text{HT-Duplicate}}^{\text{Tone}}$ is defined in Table 20-8
Implicit feedback beamforming is a technique that relies on reciprocity in the time division duplex channel to estimate the channel over which a device is transmitting based on the MIMO reference that is received from the device to which it plans to transmit. This technique allows the transmitting device to calculate a set of transmit steering matrices, $Q_k$, one for each subcarrier, which are intended to optimize the performance of the link.

Referring to Figure 20-14, beamforming transmissions from STA A to STA B using implicit techniques are enabled when STA B sends STA A a sounding PPDU, the reception of which allows STA A to form an estimate of the MIMO channel from STA B to STA A, for all subcarriers. For a TDD channel in which the forward and reverse channels are reciprocal, the channel from STA A to STA B in subcarrier $k$ is the matrix transpose of the channel from STA B to STA A in subcarrier $k$ to within a complex scaling factor, i.e., $H_{AB,k} = \rho [H_{BA,k}]^T$. Here $H_{AB,k}$ is the MIMO channel matrix from STA A to STA B at subcarrier $k$, and $H_{BA,k}$ is the channel matrix from STA B to STA A at subcarrier $k$. STA A uses this relationship to compute transmit steering matrices that are suitable for transmitting to STA B over $H_{AB,k}$.

**NOTE**—In order for the recipient of the sounding to compute steering matrices when steered or unsteered sounding is used, the steering matrices need to have the property $(H_k Q_k)(H_k Q_k)^H = H_k H_k^H$, where $X^H$ indicates the conjugate transpose of the matrix $X$.

While the over-the-air channel between the antenna(s) at one STA and the antenna(s) at a second STA is reciprocal, the observed baseband-to-baseband channel used for communication may not be, as it includes the transmit and receive chains of the STAs. Differences in the amplitude and phase characteristics of the transmit and receive chains associated with individual antennas degrade the reciprocity of the over-the-air channel and cause degradation of performance of implicit beamforming techniques. The over-the-air calibration procedure described in 9.29.2.4 may be used to restore reciprocity. The procedure provides the means for calculating a set of correction matrices that can be applied at the transmit side of a STA to correct the amplitude and phase differences between the transmit and receive chains in the STA. If this correction is done at least at the STA that serves as the beamformer, there is sufficient reciprocity for implicit feedback in the baseband-to-baseband response of the forward link and reverse channel.

Figure 20-15 illustrates the observed baseband-to-baseband channel, including reciprocity correction. Spatial mapping matrices $Q_{A,k}$ and $Q_{B,k}$ are assumed to be identity matrices here for simplicity of illustration.
NOTE—Spatial mapping matrix for sounding PPDU's are specified in 20.3.13.3.

The amplitude and phase responses of the transmit and receive chains can be expressed as diagonal matrices with complex valued diagonal entries, of the form $A_{TX,k}$ and $A_{RX,k}$ at STA A. The relationship between the baseband-to-baseband channel, $H_{AB,k}$, and the over-the-air channel, $H_{AB,k}$, is shown in Equation (20-64).

$$\hat{H}_{AB,k} = B_{RX,k} H_{AB,k} A_{TX,k}$$  \hspace{1cm} (20-64)

Similarly, the relationship between $\hat{H}_{BA,k}$ and $H_{BA,k}$ is shown in Equation (20-65).

$$\hat{H}_{BA,k} = A_{RX,k} H_{BA,k} B_{TX,k}$$  \hspace{1cm} (20-65)

As an example, consider the case where calibration is performed at both STA A and STA B. The objective is to compute correction matrices, $K_{A,k}$ and $K_{B,k}$, that restore reciprocity so that Equation (20-66) is true.

$$\hat{H}_{AB,k} K_{A,k} = \rho [\hat{H}_{BA,k} K_{B,k}]^T$$  \hspace{1cm} (20-66)

The correction matrices are diagonal matrices with complex valued diagonal entries. The reciprocity condition in Equation (20-66) is enforced when Equation (20-67) and Equation (20-68) are true.

$$K_{A,k} = \alpha_{A,k} [A_{TX,k}]^{-1} A_{RX,k}$$  \hspace{1cm} (20-67)

and

$$K_{B,k} = \alpha_{B,k} [B_{TX,k}]^{-1} B_{RX,k}$$  \hspace{1cm} (20-68)

where $\alpha_{A,k}$ and $\alpha_{B,k}$ are complex valued scaling factors.

Using these expressions for the correction matrices, the calibrated baseband-to-baseband channel between STA A and STA B is expressed as shown in Equation (20-69).
If both sides apply the correction matrices, the calibrated baseband-to-baseband channel between STA A and STA B is expressed as shown in Equation (20-70).

\[ \hat{H}_{AB,k} = \hat{H}_{AB,k}K_{A,k} = \alpha_{A,k}B_{RX,k}H_{AB,k}A_{RX,k} \]  

Equation (20-69)

Focusing on STA A, the procedure for estimating \( K_{A,k} \) is as follows:

a) STA A sends STA B a sounding PPDU, the reception of which allows STA B to estimate the channel matrices \( \hat{H}_{AB,k} \).

b) STA B sends STA A a sounding PPDU, the reception of which allows STA A to estimate the channel matrices \( \hat{H}_{BA,k} \).

c) STA B sends the quantized estimates of \( \hat{H}_{AB,k} \) to STA A.

d) STA A uses its local estimates of \( \hat{H}_{BA,k} \) and the quantized estimates of \( \hat{H}_{AB,k} \) received from STA B to compute the correction matrices \( K_{A,k} \).

NOTE—When a nonidentity matrix is used for \( Q_{A,k} \), STA A is responsible for accounting for the spatial mapping in its local channel estimate as well as in the quantized CSI fed back since the channel feedback received in step c) is actually \( \hat{H}_{AB,k}Q_{A,k} \) and not \( \hat{H}_{AB,k} \). Furthermore, since \( Q_{B,k} \) is defined in 20.3.13.3, additional steps might be taken in STA A to remove the effect of \( Q_{B,k} \) when computing the correction matrix \( K_{A,k} \).

Steps a) and b) occur over a short time interval to ensure that the channel changes as little as possible between measurements. A similar procedure is used to estimate \( K_{B,k} \) at STA B. The details of the computation of the correction matrices is implementation specific and beyond the scope of this standard.

20.3.12.3 Explicit feedback beamforming

20.3.12.3.1 General

In explicit beamforming, in order for STA A to transmit a beamformed packet to STA B, STA B measures the channel matrices and sends STA A either the effective channel, \( H_{\text{eff},k} \), or the beamforming feedback matrix, \( V_k \), for STA A to determine a steering matrix, \( Q_{\text{steer},k} = Q_kV_k \), with \( V_k \) found from \( H_kQ_k \), where \( Q_k \) is the orthonormal spatial mapping matrix that was used to transmit the sounding packet that elicited the \( V_k \) feedback. The effective channel, \( H_{\text{eff},k} = H_kQ_k \), is the product of the spatial mapping matrix used on transmit with the channel matrix. When new steering matrix \( Q_{\text{steer},k} \) is found, \( Q_{\text{steer},k} \) may replace \( Q_k \) for the next beamformed data transmission.

NOTE—\( Q_{\text{steer},k} \) is a mathematical term to update a new steering matrix for \( Q_k \) in the next beamformed data transmission.

20.3.12.3.2 CSI matrices feedback

In CSI matrices feedback, the beamformer receives the quantized MIMO channel matrix, \( H_{\text{eff}} \), from the beamformee. The beamformer then may use this matrix to compute a set of transmit steering matrices, \( Q_k \). The CSI matrix, \( H_{\text{eff}} \), shall be determined from the transmitter spatial mapper input to the receiver FFT
outputs. The beamformer shall remove the CSD in Table 20-10 from the measured channel matrix.

The matrices $H_{\text{eff}}(k)$, where $k$ is the subcarrier index, are encoded so that applying the procedure in 20.3.12.3.3 optimally reconstructs the matrix.

### 20.3.12.3.3 CSI matrices feedback decoding procedure

The received, quantized matrix $H_{\text{eff}}^k$ (of a specific subcarrier, $k$) shall be decoded as follows:

a) The real and imaginary parts of each element of the matrix, $H_{\text{eff}(m,l)}^{(R)}(k)$ and $H_{\text{eff}(m,l)}^{(I)}(k)$, are decoded as a pair of twos complement numbers to create the complex element, where $1 \leq m \leq N_r$ and $1 \leq l \leq N_c$.

b) Each element in the matrix of subcarrier $k$ is then scaled using the value in the carrier matrix amplitude field (3 bits), $M_{\text{eff}}(k)$, interpreted as a positive integer, in decibels, as follows:

1) Calculate the linear value as defined in Equation (20-71).

2) Calculate decoded values of the real and imaginary parts of the matrix element as defined in Equation (20-72) and Equation (20-73).

$$r(k) = 10^{M_{\text{eff}}(k)/20}$$  \hspace{1cm} (20-71)

$$\text{Re}\{H_{\text{eff}(m,l)}^{(R)}(k)\} = \frac{H_{\text{eff}(m,l)}^{(R)}(k)}{r(k)}$$  \hspace{1cm} (20-72)

$$\text{Im}\{H_{\text{eff}(m,l)}^{(I)}(k)\} = \frac{H_{\text{eff}(m,l)}^{(I)}(k)}{r(k)}$$  \hspace{1cm} (20-73)

### 20.3.12.3.4 Example of CSI matrices feedback encoding

The following is an example of an encoding process:

a) The maximums of the real and imaginary parts of each element of the matrix in each subcarrier are found, as defined by Equation (20-74).

$$m_{\text{eff}}(k) = \max \left\{ \max \left\{ \text{Re}\{H_{\text{eff}(m,l)}^{(R)}(k)\} \right\}_{m=1,l=1}^{m=N_r,l=N_c} , \max \left\{ \text{Im}\{H_{\text{eff}(m,l)}^{(I)}(k)\} \right\}_{m=1,l=1}^{m=N_r,l=N_c} \right\}$$  \hspace{1cm} (20-74)

b) The scaling ratio is calculated and quantized to 3 bits as defined by Equation (20-75). A linear scaler is given by Equation (20-76).

$$M_{\text{eff}}(k) = \min \left\{ 7 , \left\lfloor 20\log_{10} \left( \frac{\max \left\{ m_{\text{eff}}(z) \right\}_{z=N_{\text{eff}}}}{m_{\text{eff}}(k)} \right) \right\rfloor \right\}$$  \hspace{1cm} (20-75)

where $\left\lfloor x \right\rfloor$ is the largest integer smaller than or equal to $x$
c) The real and imaginary parts of each element in the matrix $H_{\text{eff}(m,l)}(k)$ are quantized to $N_b$ bits in two's complement encoding as defined by Equation (20-77) and Equation (20-78).

$$M_H^{\text{lin}}(k) = \frac{\max\{m_H(z)\}}{10^{M_H(k)/20}}$$

$$H_{\text{eff}(m,l)}^{(R)}(k) = \text{round}\left( \frac{\text{Re}\{H_{\text{eff}(m,l)}(k)\}}{M_H^{\text{lin}}(k)} \right) \left(2^{N_b-1} - 1\right)$$

$$H_{\text{eff}(m,l)}^{(I)}(k) = \text{round}\left( \frac{\text{Im}\{H_{\text{eff}(m,l)}(k)\}}{M_H^{\text{lin}}(k)} \right) \left(2^{N_b-1} - 1\right)$$

Each matrix is encoded using $3 + 2 \times N_b \times N_r \times N_c$ bits, where $N_r$ and $N_c$ are the number of rows and columns, respectively, in the channel matrix estimate computed by the receiving station and where $N_b$ may have the value of 4, 5, 6, or 8 bits.

**20.3.12.3.5 Noncompressed beamforming feedback matrix**

In noncompressed beamforming feedback matrix, the beamformee shall remove the space-time stream CSD in Table 20-10 from the measured channel before computing a set of matrices for feedback to the beamformer. The beamforming feedback matrices, $V(k)$, found by the beamformee are sent to the beamformer in the order of real and imaginary components per tone as specified in 8.4.1.28. The beamformer might use these matrices to determine the steering matrices, $Q_k$.

The beamformee shall encode the matrices $V(k)$ so a beamformer applying the procedure below optimally reconstructs the matrix.

The received matrix $V^q(k)$ (of a specific subcarrier $k$) shall be decoded as follows:

a) The real and imaginary parts of each element of the matrix, $V_{m,i}^{q,R}$ and $V_{m,i}^{q,I}$, shall be decoded as a pair of two's complement numbers to create the complex element, where $1 \leq m \leq N_r$ and $1 \leq l \leq N_c$.

b) The dimensions of the beamforming feedback matrices are $N_r \times N_c$, where $N_r$ and $N_c$ are the number of rows and columns, respectively, in the beamforming feedback matrix computed by the receiving station. Each matrix is encoded using $2 \times N_b \times N_r \times N_c$ bits. $N_b$ may have the value of 2, 4, 6, or 8 bits.

c) Columns $1...N_c$ of the beamforming feedback matrix correspond to spatial streams $1...N_c$, respectively. The mapping of spatial stream to modulation is defined in the MCS tables in 20.6. A transmitter shall not reorder the columns of the beamforming feedback matrices.

**20.3.12.3.6 Compressed beamforming feedback matrix**

In compressed beamforming feedback matrix, the beamformee shall remove the space-time stream CSD in Table 20-10 from the measured channel before computing a set of matrices for feedback to the beamformer. The beamforming feedback matrices, $V(k)$, found by the beamformee are compressed in the form of angles,
which are sent to the beamformer. The beamformer might use these angles to decompress the matrices and determine the steering matrices $Q_k$.

The matrix $V$ per tone shall be compressed as follows: The $N_r \times N_c$ beamforming feedback orthonormal column matrix $V$ found by the beamformer shall be represented as shown in Equation (20-79). When the number of rows and columns is equal, the orthonormal column matrix becomes a unitary matrix.

$$
V = \left[ \prod_{i=1}^{\min(N_c,N_r-1)} D \left( 1_{i-1} e^{j\theta_{i,i}} \ldots e^{j\theta_{i,N_r-1}} 1 \right) \prod_{i=i+1}^{N_r} G_i^T(\psi_i) \right] \tilde{I}_{N_r \times N_c} \tag{20-79}
$$

The matrix $D \left( 1_{i-1} e^{j\theta_{i,i}} \ldots e^{j\theta_{i,N_r-1}} 1 \right)$ is an $N_r \times N_r$ diagonal matrix, where $1_{i-1}$ represents a sequence of ones with length of $i-1$, as shown in Equation (20-80).

$$
D \left( 1_{i-1} e^{j\theta_{i,i}} \ldots e^{j\theta_{i,N_r-1}} 1 \right) = \begin{bmatrix}
I_{i-1} & 0 & \ldots & 0 \\
0 & e^{j\theta_{i,i}} & 0 & \ldots & 0 \\
\vdots & \ddots & \ddots & \ddots & \vdots \\
0 & 0 & e^{j\theta_{i,N_r-1}} & 0 & 0 \\
0 & 0 & 0 & 0 & 1
\end{bmatrix} \tag{20-80}
$$

The matrix $G_i(\psi)$ is an $N_r \times N_r$ Givens rotation matrix as shown in Equation (20-81).

$$
G_i(\psi) = \begin{bmatrix}
I_{i-1} & 0 & 0 & 0 & 0 \\
0 & \cos(\psi) & 0 & \sin(\psi) & 0 \\
0 & 0 & I_{i-1-i} & 0 & 0 \\
0 & -\sin(\psi) & 0 & \cos(\psi) & 0 \\
0 & 0 & 0 & 0 & I_{N_r-i}
\end{bmatrix} \tag{20-81}
$$

where each $I_m$ is an $m \times m$ identity matrix, and $\cos(\psi)$ and $\sin(\psi)$ are located at row $l$ and column $i$. $\tilde{I}_{N_r \times N_c}$ is an identity matrix padded with 0s to fill the additional rows or columns when $N_r \neq N_c$.

For example, a $4 \times 2$ $V$ matrix has the representation shown in Equation (20-82).

$$
V = \begin{bmatrix}
e^{j\theta_{11}} & 0 & 0 & 0 \\
e^{j\theta_{21}} & 0 & 0 & 1 \\
e^{j\theta_{31}} & 0 & 0 & 1 \\
e^{j\theta_{41}} & 0 & 0 & 1
\end{bmatrix} \begin{bmatrix}
\cos \psi_{21} & \sin \psi_{21} & 0 & 0 \\
-\sin \psi_{21} & \cos \psi_{21} & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1
\end{bmatrix}^T \begin{bmatrix}
\cos \psi_{31} & 0 & \sin \psi_{31} & 0 \\
0 & 1 & 0 & 0 \\
-\sin \psi_{31} & 0 & \cos \psi_{31} & 0 \\
0 & 0 & 0 & 1
\end{bmatrix} \begin{bmatrix}
\cos \psi_{41} & 0 & \sin \psi_{41} & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
-\sin \psi_{41} & 0 & \cos \psi_{41} & 0
\end{bmatrix} \begin{bmatrix}
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1
\end{bmatrix}^T \begin{bmatrix}
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1
\end{bmatrix} \begin{bmatrix}
e^{j\theta_{12}} & 0 & 0 & 0 \\
e^{j\theta_{22}} & 0 & 0 & 1 \\
e^{j\theta_{32}} & 0 & 0 & 1 \\
e^{j\theta_{42}} & 0 & 0 & 1
\end{bmatrix} \tag{20-82}
$$
The procedure for finding a compressed $V$ matrix is described as follows:

A $N_r \times N_c$ beamforming feedback orthonormal column matrix $V$ is column-wise phase invariant because the steering matrix needs a reference in phase per each column. When the number of rows and columns is equal, the orthonormal column matrix becomes a unitary matrix. In other words, $V$ is equivalent to $\tilde{V}D$, where $\tilde{D}$ is a column-wise phase shift matrix such as $\tilde{D} = \text{diag}(e^{j\theta_1}, e^{j\theta_2}, \ldots, e^{j\theta_N})$. When the beamformee estimates the channel, it may find $\tilde{V}$ for the beamforming feedback matrix for the beamformer, but it should send $\tilde{V}\tilde{D}$ back to the beamformer, where $V = \tilde{V}\tilde{D}$. The angle, $\theta_i$, in $\tilde{D}$ is found to make the last row of $\tilde{V}\tilde{D}$ to be non-negative real numbers.

The angles $\phi_{1,1}, \ldots, \phi_{N_r-1,1}$ in the diagonal matrix $D_1(e^{j\phi_{1,1}} \ldots e^{j\phi_{N_r-1,1}} 1)^*$ shall satisfy the constraint that all elements in the first column of $D_1^*V$ are non-negative real numbers. Now, the first column of $(G_{N_r,1}G_{N_r,2}D_1^*)^T$ can be $\begin{bmatrix} 1 & 0 & \ldots & 0 \end{bmatrix}$ by the Givens rotations $G_{i1}$ such as shown in Equation (20-83).

$$
\begin{bmatrix}
\cos\psi_{N_r,1} & 0 & 0 & \sin\psi_{N_r,1} \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
-\sin\psi_{N_r,1} & 0 & 0 & \cos\psi_{N_r,1}
\end{bmatrix}
\begin{bmatrix}
\cos\psi_{N_r,1} & 0 & 0 & \sin\psi_{N_r,1} \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
-\sin\psi_{N_r,1} & 0 & 0 & \cos\psi_{N_r,1}
\end{bmatrix}
\begin{bmatrix}
\cos\psi_{21} & 0 & 0 & \sin\psi_{21} \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
-\sin\psi_{21} & 0 & 0 & \cos\psi_{21}
\end{bmatrix}
\begin{bmatrix}
e^{j\phi_{1,1}} & 0 & 0 & 0 \\
0 & e^{j\phi_{2,1}} & 0 & 0 \\
0 & 0 & e^{j\phi_{3,1}} & 0 \\
0 & 0 & 0 & e^{j\phi_{N_r-1,1}}
\end{bmatrix}
\begin{bmatrix}1 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0
\end{bmatrix}
= V
\begin{bmatrix}I_{N_r,1}^* & 0 & 0 & 0 \\
0 & I_{N_r,2}^* & 0 & 0 \\
0 & 0 & I_{N_r,3}^* & 0 \\
0 & 0 & 0 & I_{N_r,4}^*
\end{bmatrix}
\begin{bmatrix}
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0
\end{bmatrix}
$$

(20-83)

For a new $(N_r-1) \times (N_c-1)$ submatrix $V_2$, this process is applied in the same way. Then, the angles $\phi_{2,2}, \ldots, \phi_{N_r-1,2}$ in the diagonal matrix $D_2(e^{j\phi_{2,2}} \ldots e^{j\phi_{N_r-1,2}} 1)^*$ shall satisfy the constraint that all elements in the second column of $D_2^*V$ are non-negative real numbers. Now, the first two columns of $(G_{N_r,2}G_{N_r,3}G_{N_r,4}D_2^*)^T$ can be $\tilde{I}_{N_r,2}$ by the Givens rotations $G_{i2}$ such as shown in Equation (20-84).

$$
\begin{bmatrix}
1 & 0 & 0 & 0 \\
0 & \cos\psi_{N_r,2} & 0 & \sin\psi_{N_r,2} \\
0 & 0 & 1 & 0 \\
0 & -\sin\psi_{N_r,2} & 0 & \cos\psi_{N_r,2}
\end{bmatrix}
\begin{bmatrix}
1 & 0 & 0 & 0 \\
0 & \cos\psi_{22} & 0 & \sin\psi_{22} \\
0 & 0 & 1 & 0 \\
0 & -\sin\psi_{22} & 0 & \cos\psi_{22}
\end{bmatrix}
\begin{bmatrix}
1 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0
\end{bmatrix}
\times G_{N_r,1}G_{N_r,2}G_{N_r,3}D_2^* \times V
= \begin{bmatrix}
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1
\end{bmatrix}
\begin{bmatrix}
V_1^* & 0 & 0 & 0 \\
0 & V_2^* & 0 & 0 \\
0 & 0 & V_3^* & 0 \\
0 & 0 & 0 & V_4^*
\end{bmatrix}
$$

(20-84)

This process continues until the first $N_c$ columns of the right side matrix become $\tilde{I}_{N_r \times N_c}$. When $N_c < N_r$, this process does not need to continue because $V_{N_c+1}^*$ is nulled out by $\tilde{I}_{N_r \times N_c}$. Then, by multiplying the complex conjugate transpose of the products of the $D_1$ and $G_{i1}$ matrices on the left, $V$ can be expressed as shown in Equation (20-85).
\[ V = D_1G_{21}^T G_{31}^T \cdots G_{N_j1}^T \times D_2G_{22}^T G_{32}^T \cdots G_{N_j2}^T \times \cdots \times D_pG_{p+1,p}^T G_{p+2,p}^T \cdots G_{N_r,p}^T \times \hat{I}_{N_r \times N_c} \]  \hspace{1cm} (20-85)

where \( p = \min(N_c, N_r - 1) \), which can be written in short form as in Equation (20-79).

The angles found from the decomposition process above, e.g., the values of \( \psi_{i,j} \) and \( \phi_{k,l} \), are quantized as described in 8.5.12.8.

Columns \( 1 \ldots N_c \) of the beamforming feedback matrix correspond to spatial streams \( 1 \ldots N_c \), respectively. The mapping of spatial stream to modulation is defined in the MCS tables in 20.6. A transmitter shall not reorder the columns of the beamforming feedback matrices in determining steering matrices.

### 20.3.13 HT Preamble format for sounding PPDUs

#### 20.3.13.1 General

The MIMO channel measurement takes place in every PPDU as a result of transmitting the HT-LTFs as part of the PLCP preamble. The number of HT-LTFs transmitted shall be determined by the number of space-time streams transmitted unless additional dimensions are optionally sounded using HT-ELTFs and these are transmitted using the same spatial transformation that is used for the Data field of the HT PPDU. The use of the same spatial transformation enables the computation of the spatial equalization at the receiver.

When the number of space-time streams, \( N_{STS} \), is less than the number of transmit antennas, or less than \( \min(N_{TX}, N_{RX}) \), sending only \( N_{STS} \) HT-LTFs does not allow the receiver to recover a full characterization of the MIMO channel, even though the resulting MIMO channel measurement is sufficient for receiving the Data field of the HT PPDU. However, there are several cases where it is desirable to obtain as full a characterization of the channel as possible, thus requiring the transmission of a sufficient number of HT-LTFs to sound the full dimensionality of the channel, which is in some cases \( N_{TX} \) and in other cases \( \min(N_{TX}, N_{RX}) \). These cases of MIMO channel measurement are referred to as **MIMO channel sounding**. A sounding packet may be used to sound available channel dimensions. A sounding PPDU is identified by setting the Not Sounding field in the HT-SIG to 0. A sounding PPDU may have any allowed number of HT-LTFs satisfying \( N_{LTF} \geq N_{STS} \). In general, if the Not Sounding field in the HT-SIG is equal to 0 and \( N_{LTF} > N_{STS} \), HT-ELTFs are used, except where \( N_{SS} = 3 \) and \( N_{LTF} = 4 \) or in an NDP.

#### 20.3.13.2 Sounding with a NDP

A STA may sound the channel using a NDP (indicated by the HT Length field in the HT-SIG equal to 0) with the Not Sounding field equal to 0. The number of LTFs is the number implied by the MCS, which shall indicate two or more spatial streams. The last HT-LTF of an NDP shall not be followed by a Data field (see Figure 20-16).

It is optional for a STA to process an NDP.

![Figure 20-16—Example of an NDP used for sounding](image-url)
20.3.13.3 Sounding PPDU for calibration

In the case of a bidirectional calibration exchange, two STAs exchange sounding PPDU, the exchange of which enables the receiving STA to compute an estimate of the MIMO channel matrix $H_k$ for each subcarrier $k$. In general, in an exchange of calibration messages, the number of spatial streams is less than the number of transmit antennas. In such cases, HT-ELTFs are used. In the case of sounding PPDU for calibration, the antenna mapping matrix shall be as shown in Equation (20-86).

$$Q_k = C_{\text{CSFD}}(k)P_{\text{CAL}}$$  (20-86)

where

- $C_{\text{CSFD}}(k)$ is a diagonal cyclic shift matrix in which the diagonal elements carry frequency-domain representation of the cyclic shifts given in Table 20-9
- $P_{\text{CAL}}$ is one of the following unitary matrices:
  - For $N_{TX} = 1$, $P_{\text{CAL}} = 1$
  - For $N_{TX} = 2$, $P_{\text{CAL}} = \frac{\sqrt{2}}{2} \begin{bmatrix} 1 & -1 \\ 1 & 1 \end{bmatrix}$
  - For $N_{TX} = 3$, $P_{\text{CAL}} = \frac{\sqrt{3}}{3} \begin{bmatrix} 1 & 1 & 1 \\ 1 & e^{-j2\pi/3} & e^{j4\pi/3} \\ 1 & e^{j4\pi/3} & e^{-j2\pi/3} \end{bmatrix}$
  - For $N_{TX} = 4$, $P_{\text{CAL}} = \frac{1}{2} \begin{bmatrix} 1 & -1 & 1 & 1 \\ 1 & 1 & -1 & 1 \\ 1 & 1 & 1 & -1 \\ -1 & 1 & 1 & 1 \end{bmatrix}$

20.3.13.4 Sounding PPDU for channel quality assessment

In response to the reception of an MRQ, sent by STA A to STA B, the responding STA B returns to the requesting STA A an MCS selection that STA B determines to be a suitable MCS for STA A to use in subsequent transmissions to STA B. In determining the MCS, STA B performs a channel quality assessment, which entails using whatever information STA B has about the channel, such as an estimate of the MIMO channel derived from the sounding PPDU that carries the MRQ. To enable this calculation, the MRQ is sent in conjunction with a sounding PPDU.

The STA sending the MRQ (STA A) determines how many HT-LTFs to send, and whether to use HT-ELTFs or an NDP, based on the Transmit Beamforming Capabilities field, number of space-time streams used in the PPDU carrying the MRQ, the number of transmit chains it is using ($N_{TX}$), whether the transmit and receive STAs support STBC, and in some cases, the number of receive chains at the responding STA ($N_{RX}$).

The maximum number of available space-time streams is set by the number of transmit and receive chains and the STBC capabilities of the transmitter and receiver, as is shown in Table 20-21. While the number of receive chains at a STA is not communicated in a capabilities indicator, the maximum number of space-time streams supported may be inferred from the MCS capabilities and the STBC capabilities of the receiving STA. When the number of receive chains is known at the transmitter, the number of HT-LTFs sent to obtain a full channel quality assessment is determined according to the maximum number of space-time streams indicated in Table 20-21. The number of HT-LTFs to use in conjunction with the indicated number of space-time streams is determined according to 20.3.9.4.6.
If the requesting STA A sends an MRQ in a PPDU that uses fewer space-time streams in the data portion than the maximum number of space-time streams possible given the number of antennas at STA A and the responding STA B, the channel quality assessment made by STA B may be based on the HT-DLTFs alone. In this case, the MFB is limited to MCSs using the number of streams used in the Data field of the HT PPDU, or fewer. To determine whether an MCS should be chosen that uses more spatial streams than the PPDU containing the MRQ, it is necessary for the requesting STA A to either use HT-ELTFs (i.e., send the MRQ in a staggered sounding PPDU) or use an NDP (i.e., send the MRQ in conjunction with an NDP).

The sounding PPDU may have nonidentity spatial mapping matrix $Q_k$. For different receiving STAs, $Q_k$ may vary.

### 20.3.14 Regulatory requirements

Wireless LANs (WLANs) implemented in accordance with this standard are subject to equipment certification and operating requirements established by regional and national regulatory administrations. The PMD specification establishes minimum technical requirements for interoperability, based upon established regulations at the time this standard was issued. These regulations are subject to revision or may be superseded. Requirements that are subject to local geographic regulations are annotated within the PMD specification. Regulatory requirements that do not affect interoperability are not addressed in this standard. Implementers are referred to the regulatory sources in Annex D for further information. Operation in countries within defined regulatory domains may be subject to additional or alternative national regulations.

### 20.3.15 Channel numbering and channelization

#### 20.3.15.1 General

The STA may operate in the 5 GHz band and/or 2.4 GHz band. When using 20 MHz channels, it uses channels defined in 18.3.8.4 (5 GHz band) or 17.4.6 (2.4 GHz band). When using 40 MHz channels, it can operate in the channels defined in 20.3.15.2 and 20.3.15.3.

The set of valid operating channel numbers by regulatory domain is defined in Annex E.

#### 20.3.15.2 Channel allocation in the 2.4 GHz Band

Channel center frequencies are defined at every integral multiple of 5 MHz in the 2.4 GHz band. The relationship between center frequency and channel number is given by Equation (20-87).

---

---

The sounding PPDU may have nonidentity spatial mapping matrix $Q_k$. For different receiving STAs, $Q_k$ may vary.
where
\[ n_{ch} = 1, 2, \ldots, 13 \]

### 20.3.15.3 Channel allocation in the 5 GHz band

Channel center frequencies are defined at every integral multiple of 5 MHz above 5 GHz. The relationship between center frequency and channel number is given in Equation (20-88).

\[
\text{Channel center frequency} = \text{Channel starting frequency} + 5 \times n_{ch} \text{(MHz)} \tag{20-88}
\]

where
\[ n_{ch} = 1, \ldots, 200 \]

Channel starting frequency is defined as \text{dot11ChannelStartingFactor} \times 500 \text{ kHz} or is defined as 5.000 GHz for systems where \text{dot11OperatingClassesRequired} is false or not defined. A channel center frequency of 5.000 GHz shall be indicated by \text{dot11ChannelStartingFactor} = 8000 and \( n_{ch} = 200 \).

### 20.3.15.4 40 MHz channelization

The set of valid operating channel numbers by regulatory domain is defined in Annex E. The 40 MHz channels are specified by two fields: \((N_{primary\_ch}, \text{Secondary})\). The first field represents the channel number of the primary channel, and the second field indicates whether the secondary channel is above or below the primary channel (1 indicates above, \(-1\) indicates below). The secondary channel number shall be \( N_{primary\_ch} + \text{Secondary} \times 4 \).

For example, a 40 MHz channel consisting of 40 MHz channel number 36 and Secondary 1 specifies the primary channel is 36 and the secondary channel is 40.

### 20.3.16 Transmit and receive in-band and out-of-band spurious transmissions

The OFDM PHY shall conform to in-band and out-of-band spurious emissions as set by regulatory bodies.

### 20.3.17 Transmitter RF delay

The transmitter RF delay shall follow 18.3.8.6.

### 20.3.18 Slot time

The slot time shall follow 18.3.8.7 for 5 GHz bands and 19.4.5 for 2.4 GHz bands.

### 20.3.19 Transmit and receive port impedance

The transmit and receive antenna port impedance for each transmit and receive antenna shall follow 18.3.8.8.
20.3.20 PMD transmit specification

20.3.20.1 Transmit spectrum mask

NOTE 1—In the presence of additional regulatory restrictions, the device has to meet both the regulatory requirements and the mask defined in this subclause, i.e., its emissions can be no higher at any frequency offset than the minimum of the values specified in the regulatory and default masks.

NOTE 2—The transmit spectral mask figures in this subclause are not drawn to scale.

For the 2.4 GHz band, when transmitting in a 20 MHz channel, the transmitted spectrum shall have a 0 dBr (dB relative to the maximum spectral density of the signal) bandwidth not exceeding 18 MHz, –20 dBr at 11 MHz frequency offset, –28 dBr at 20 MHz frequency offset, and the maximum of –45 dBr and –53 dBm/MHz at 30 MHz frequency offset and above. The transmitted spectral density of the transmitted signal shall fall within the spectral mask, as shown in Figure 20-17. The measurements shall be made using a 100 kHz resolution bandwidth and a 30 kHz video bandwidth.

![Figure 20-17—Transmit spectral mask for 20 MHz transmission in the 2.4 GHz band](image)

For the 2.4 GHz band, when transmitting in a 40 MHz channel, the transmitted spectrum shall have a 0 dBr bandwidth not exceeding 38 MHz, –20 dBr at 21 MHz frequency offset, –28 dBr at 40 MHz offset, and the maximum of –45 dBr and –56 dBm/MHz at 60 MHz frequency offset and above. The transmitted spectral density of the transmitted signal shall fall within the spectral mask, as shown in Figure 20-18.

For the 5 GHz band, when transmitting in a 20 MHz channel, the transmitted spectrum shall have a 0 dBr (dB relative to the maximum spectral density of the signal) bandwidth not exceeding 18 MHz, –20 dBr at 11 MHz frequency offset, –28 dBr at 20 MHz frequency offset, and the maximum of –40 dBr and –53 dBm/MHz at 30 MHz frequency offset and above. The transmitted spectral density of the transmitted signal shall fall within the spectral mask, as shown in Figure 20-19. The measurements shall be made using a 100 kHz resolution bandwidth and a 30 kHz video bandwidth.

For the 5 GHz band, when transmitting in a 40 MHz channel, the transmitted spectrum shall have a 0 dBr bandwidth not exceeding 38 MHz, –20 dBr at 21 MHz frequency offset, –28 dBr at 40 MHz offset, and the maximum of –40 dBr and –56 dBm/MHz at 60 MHz frequency offset and above. The transmitted spectral density of the transmitted signal shall fall within the spectral mask, as shown in Figure 20-20.

Transmission with CH_OFF_20U, CH_OFF_20L, or CH_OFF_40 shall conform to the same mask that is used for the 40 MHz channel.
Figure 20-18—Transmit spectral mask for a 40 MHz channel in the 2.4 GHz band

Figure 20-19—Transmit spectral mask for 20 MHz transmission in the 5 GHz band

Figure 20-20—Transmit spectral mask for a 40 MHz channel in the 5 GHz band
20.3.20.2 Spectral flatness

In a 20 MHz channel and in corresponding 20 MHz transmission in a 40 MHz channel, the average energy of the constellations in each of the subcarriers with indices –16 to −1 and +1 to +16 shall deviate no more than ±4 dB from their average energy. The average energy of the constellations in each of the subcarriers with indices –28 to −17 and +17 to +28 shall deviate no more than +4/–6 dB from the average energy of subcarriers with indices –16 to −1 and +1 to +16.

In a 40 MHz transmission (excluding PPDUs in MCS 32 format and non-HT duplicate format), the average energy of the constellations in each of the subcarriers with indices –42 to −2 and +2 to +42 shall deviate no more than ±4 dB from their average energy. The average energy of the constellations in each of the subcarriers with indices –43 to −58 and +58 to +43 shall deviate no more than +4/–6 dB from the average energy of subcarriers with indices –42 to −2 and +2 to +42.

In MCS 32 format and non-HT duplicate format, the average energy of the constellations in each of the subcarriers with indices –42 to −33, −31 to −6, +6 to +31, and +33 to +42 shall deviate no more than ±4 dB from their average energy. The average energy of the constellations in each of the subcarriers with indices –43 to −58 and +58 to +43 shall deviate no more than +4/–6 dB from the average energy of subcarriers with indices –42 to −33, −31 to −6, +6 to +31, and +33 to +42.

The tests for the spectral flatness requirements may be performed with spatial mapping \( Q_k = I \) (see 20.3.11.11.2).

20.3.20.3 Transmit power

The maximum allowable output power is measured in accordance with practices specified by the appropriate regulatory bodies.

20.3.20.4 Transmit center frequency tolerance

The transmitter center frequency tolerance shall be ±20 ppm maximum for the 5 GHz band and ±25 ppm maximum for the 2.4 GHz band. The different transmit chain center frequencies (LO) and each transmit chain symbol clock frequency shall all be derived from the same reference oscillator.

20.3.20.5 Packet alignment

If no signal extension is required (see 20.3.2), the receiver shall emit a PHY-CCA.indication(idle) primitive (see 7.3.5.11) at the 4 \( \mu \)s boundary following the reception of the last symbol of the packet. If a signal extension is required, the receiver shall emit a PHY-CCA.indication(idle) primitive a duration of \( a \text{SignalExtension} \) \( \mu \)s after the 4 \( \mu \)s boundary following the reception of the last symbol of the packet. This situation is illustrated for an HT-greenfield format packet using short GI in Figure 20-21.

If no signal extension is required, the transmitter shall emit a PHY-TXEND.confirm primitive (see 7.3.5.8) at the 4 \( \mu \)s boundary following the trailing boundary of the last symbol of the packet on the air. If a signal extension is required, the transmitter shall emit a PHY-TXEND.confirm primitive (see 7.3.5.8) a duration of \( a \text{SignalExtension} \) \( \mu \)s after the 4 \( \mu \)s boundary following the trailing boundary of the last symbol of the packet on the air. This situation is illustrated in Figure 20-21.
20.3.20.6 Symbol clock frequency tolerance

The symbol clock frequency tolerance shall be ± 20 ppm maximum for 5 GHz bands and ± 25 ppm for 2.4 GHz bands. The transmit center frequency and the symbol clock frequency for all transmit antennas shall be derived from the same reference oscillator.

20.3.20.7 Modulation accuracy

20.3.20.7.1 Introduction to modulation accuracy tests

Transmit modulation accuracy specifications are described in 20.3.20.7.2 and 20.3.20.7.3. The test method is described in 20.3.20.7.4.

20.3.20.7.2 Transmit center frequency leakage

The transmitter center frequency leakage shall follow 18.3.9.7.2 for all transmissions in a 20 MHz channel width. For transmissions in a 40 MHz channel width, the center frequency leakage shall not exceed –20 dB relative to overall transmitted power, or, equivalently, 0 dB relative to the average energy of the rest of the subcarriers. For upper or lower 20 MHz transmissions in a 40 MHz channel, the center frequency leakage (center of a 40 MHz channel) shall not exceed –17 dB relative to overall transmitted power, or, equivalently, 0 dB relative to the average energy of the rest of the subcarriers. The transmit center frequency leakage is specified per antenna.

20.3.20.7.3 Transmitter constellation error

The relative constellation frame-averaged RMS error, calculated first by averaging over subcarriers, OFDM frames, and spatial streams, shall not exceed a data-rate-dependent value according to Table 20-22. The number of spatial streams under test shall be equal to the number of utilized transmitting STA antenna (output) ports and also equal to the number of utilized testing instrumentation input ports. In the test, $N_{SS} = N_{STS}$ with EQM MCSs shall be used. Each output port of the transmitting STA shall be connected through a cable to one input port of the testing instrumentation. The same requirement applies both to 20 MHz channels and 40 MHz channels.

Note that Signal Extension field is only present in some PPDU formats. See 20.3.2.
20.3.20.7.4 Transmitter modulation accuracy (EVM) test

The transmit modulation accuracy test shall be performed by instrumentation capable of converting the transmitted signals into a stream of complex samples at 40 Msample/s or more, with sufficient accuracy in terms of I/Q arm amplitude and phase balance, dc offsets, phase noise, and analog-to-digital quantization noise. Each transmit chain is connected directly through a cable to the setup input port. A possible embodiment of such a setup is converting the signals to a low intermediate frequency with a microwave synthesizer, sampling the signal with a digital oscilloscope, and decomposing it digitally into quadrature components. The sampled signal shall be processed in a manner similar to an actual receiver, according to the following steps, or an equivalent procedure:

a) Detect the start of frame.

b) Detect the transition from short sequences to channel estimation sequences, and establish fine timing (with one sample resolution).

c) Estimate the coarse and fine frequency offsets.

d) Derotate the frame according to estimated frequency offset.

e) Estimate the complex channel response coefficients for each of the subcarriers and each of the transmit chains.

f) For each of the data OFDM symbols, transform the symbol into subcarrier received values, estimate the phase from the pilot subcarriers in all spatial streams, derotate the subcarrier values according to estimated phase, group the results from all the receiver chains in each subcarrier to a vector, multiply the vector by a zero-forcing equalization matrix generated from the channel estimated during the channel estimation phase.

g) For each data-carrying subcarrier in each spatial stream, find the closest constellation point and compute the Euclidean distance from it.

h) Compute the average of the RMS of all errors in a frame. It is given by Equation (20-89).

\[
Error_{RMS} = \frac{\sum_{i=1}^{N_{f}} \sum_{t=1}^{N_{t}} \sum_{n=1}^{N_{n}} \left[ \left( I(t_p, l_p, s_p, l_s) - I_0(l_p, l_s, s_p, l_s) \right)^2 + \left( Q(t_p, l_p, s_p, l_s) - Q_0(l_p, l_s, s_p, l_s) \right)^2 \right]}{N_{SYM} \times N_{SS} \times N_{ST} \times P_0} \times \frac{1}{N_f}
\]

(20-89)

where

- \( N_f \) is the number of frames for the measurement
$I_0(i_p, i_s, i_{ss}, i_{sc})$, $Q_0(i_p, i_s, i_{ss}, i_{sc})$ denotes the ideal symbol point in the complex plane in subcarrier $i_{sc}$, spatial stream $i_{ss}$, and OFDM symbol $i_s$ of frame $i_f$

$I(i_p, i_s, i_{ss}, i_{sc}), Q(i_p, i_s, i_{ss}, i_{sc})$ denotes the observed symbol point in the complex plane in subcarrier $i_{sc}$, spatial stream $i_{ss}$, and OFDM symbol $i_s$ of frame $i_f$

$P_0$ is the average power of the constellation

The vector error on a phase plane is shown in Figure 18-16.

The test shall be performed over at least 20 frames ($N_f$), and the average of the RMS shall be taken. The frames under test shall be at least 16 OFDM symbols long. Random data shall be used for the symbols.

### 20.3.20.8 Time of Departure accuracy

The Time of Departure accuracy test evaluates $\text{TIME}_{-}\text{OF}_{-}\text{DEPARTURE}$ against $\text{aTxPmdTxStartRMS}$ and $\text{aTxPmdTxStartRMS}$ against $\text{TIME}_{-}\text{OF}_{-}\text{DEPARTURE}_{-}\text{ACCURACY}_{-}\text{TEST}_{-}\text{THRESH}$ as defined in Annex T with the following test parameters:

- **MULTICHANNEL_SAMPLING_RATE** is:
  
  $$
  20 \times 10^6 \left(1 + \left\lfloor \frac{f_H - f_L}{20 \text{ MHz}} \right\rfloor \right) \text{ sample/s}, \text{ for a CH\textunderscore BANDWIDTH parameter equal to HT\textunderscore CBW20}
  $$
  
  $$
  40 \times 10^6 \left(1 + \left\lfloor \frac{f_H - f_L}{40 \text{ MHz}} \right\rfloor \right) \text{ sample/s, for a CH\textunderscore BANDWIDTH parameter equal to HT\textunderscore CBW40}
  $$

  where
  
  $f_H$ is the nominal center frequency in Hz of the highest channel in the channel set
  
  $f_L$ is the nominal center frequency in Hz of the lowest channel in the channel set, the channel set is the set of channels upon which frames providing measurements are transmitted, the channel set comprises channels uniformly spaced across $f_H - f_L \geq 50$ MHz

  \[ \left\lfloor x \right\rfloor \] equals the smallest integer equal to or larger than $x$.

- **FIRST\textunderscore TRANSITION\textunderscore FIELD** is L-STF (for HT\textunderscore mixed\textunderscore format) or HT\textunderscore GF\textunderscore STF (for HT\textunderscore greenfield format)

- **SECOND\textunderscore TRANSITION\textunderscore FIELD** is L-LTF (for HT\textunderscore mixed\textunderscore format) or HT\textunderscore GF\textunderscore LTF1 (for HT\textunderscore greenfield format)

- **TRAINING\textunderscore FIELD** is L-LTF (for HT\textunderscore mixed\textunderscore format) or HT\textunderscore GF\textunderscore LTF1 (for HT\textunderscore greenfield format) windowed in a manner which should approximate the windowing described in 18.3.2.5 with $T_{TR} = 100$ ns.

- **TIME\textunderscore OF\textunderscore DEPARTURE\textunderscore ACCURACY\textunderscore TEST\textunderscore THRESH** is 80 ns (for a CH\textunderscore BANDWIDTH parameter equal to HT\textunderscore CBW20) or 80 ns (for a CH\textunderscore BANDWIDTH parameter equal to HT\textunderscore CBW40).

**NOTE**—The indicated windowing applies to the time of departure accuracy test equipment, and not the transmitter or receiver.

### 20.3.21 HT PMD receiver specification

#### 20.3.21.1 Receiver minimum input sensitivity

The packet error ratio (PER) shall be less than 10% for a PSDU length of 4096 octets with the rate-dependent input levels listed in Table 20-23 or less. The minimum input levels are measured at the antenna connectors and are referenced as the average power per receive antenna. The number of spatial streams under test shall be equal to the number of utilized transmitting STA antenna (output) ports and also equal to the number of utilized device under test input ports. Each output port of the transmitting STA shall be connected through a cable to one input port of the device under test. The test in this subclause and the
minimum sensitivity levels specified in Table 20-23 apply only to non-STBC modes, MCSs 0–31, 800 ns GI, and BCC.

20.3.21.2 Adjacent channel rejection

For all transmissions in a 20 MHz channel width, the adjacent channel rejection shall be measured by setting the desired signal's strength 3 dB above the rate-dependent sensitivity specified in Table 20-23 and raising the power of the interfering signal until 10% PER is caused for a PSDU length of 4096 octets. The power difference between the interfering channel and the desired channel is the corresponding adjacent channel rejection. The adjacent channel center frequencies shall be separated by 20 MHz when operating in the 5 GHz band, and the adjacent channel center frequencies shall be separated by 25 MHz when operating in the 2.4 GHz band.

For all transmissions in a 40 MHz channel width, the adjacent channel rejection shall be measured by setting the desired signal's strength 3 dB above the rate-dependent sensitivity specified in Table 20-23 and raising the power of the interfering signal until 10% PER is caused for a PSDU length of 4096 octets. The power difference between the interfering channel and the desired channel is the corresponding adjacent channel rejection. The adjacent channel center frequencies shall be separated by 40 MHz.

The interfering signal in the adjacent channel shall be a conformant OFDM signal, unsynchronized with the signal in the channel under test. For a conforming OFDM PHY, the corresponding rejection shall be no less than specified in Table 20-23. The interference signal shall have a minimum duty cycle of 50%.

The test in this subclause and the adjacent channel rejection levels specified in Table 20-23 apply only to non-STBC modes, MCSs 0–31, 800 ns GI, and BCC.

20.3.21.3 Nonadjacent channel rejection

For all transmissions in a 20 MHz channel width in the 5 GHz band, the nonadjacent channel rejection shall be measured by setting the desired signal's strength 3 dB above the rate-dependent sensitivity specified in Table 20-23 and raising the power of the interfering signal until a 10% PER occurs for a PSDU length of 4096 octets. The power difference between the interfering channel and the desired channel is the
corresponding nonadjacent channel rejection. The nonadjacent channel center frequencies shall be separated by 40 MHz or more.

For all transmissions in a 40 MHz channel width in the 5 GHz band, the nonadjacent channel rejection shall be measured by setting the desired signal's strength 3 dB above the rate-dependent sensitivity specified in Table 20-23 and raising the power of the interfering signal until a 10% PER occurs for a PSDU length of 4096 octets. The power difference between the interfering channel and the desired channel is the corresponding nonadjacent channel rejection. The nonadjacent channel center frequencies shall be separated by 80 MHz or more.

The interfering signal in the nonadjacent channel shall be a conformant OFDM signal, unsynchronized with the signal in the channel under test. For a conforming OFDM PHY, the corresponding rejection shall be no less than specified in Table 20-23. The interference signal shall have a minimum duty cycle of 50%. The nonadjacent channel rejection for transmissions in a 20 MHz or 40 MHz channel width is applicable only to the 5 GHz band.

The test in this subclause and the nonadjacent channel rejection level specified in Table 20-23 apply only to non-STBC modes, MCSs 0–31, 800 ns GI, and BCC.

20.3.21.4 Receiver maximum input level

The receiver shall provide a maximum PER of 10% at a PSDU length of 4096 octets, for a maximum input level of –30 dBm in the 5 GHz band and –20 dBm in the 2.4 GHz band, measured at each antenna for any baseband modulation.

20.3.21.5 CCA sensitivity

20.3.21.5.1 CCA sensitivity for non-HT PPDUs

CCA sensitivity requirements for non-HT PPDUs in the primary channel are described in 18.3.10.6 and 19.4.7.

20.3.21.5.2 CCA sensitivity in 20 MHz

For an HT STA with the operating channel width equal to 20 MHz, the start of a valid 20 MHz HT signal at a receive level equal to or greater than the minimum modulation and coding rate sensitivity of –82 dBm shall cause the PHY to set PHY-CCA.indicate(BUSY) with a probability > 90% within 4 µs. The receiver shall hold the CCA signal busy for any signal 20 dB or more above the minimum modulation and coding rate sensitivity (–82 + 20 = –62 dBm) in the 20 MHz channel.

A receiver that does not support the reception of HT-GF format PPDUs shall hold the CCA signal busy (PHY_CCA.indicate(BUSY)) for any valid HT-GF signal in the 20 MHz channel at a receive level equal to or greater than –72 dBm.

20.3.21.5.3 CCA sensitivity in 40 MHz

This subclause describes the CCA sensitivity requirements for an HT STA with the operating channel width equal to 40 MHz.

The receiver of a 20/40 MHz STA with the operating channel width equal to 40 MHz shall provide CCA on both the primary and secondary channels.

When the secondary channel is idle, the start of a valid 20 MHz HT signal in the primary channel at a receive level equal to or greater than the minimum modulation and coding rate sensitivity of –82 dBm shall
cause the PHY to set PHY-CCA.indicate(BUSY, {primary}) with a probability > 90% within 4 μs. The start of a valid 40 MHz HT signal that occupies both the primary and secondary channels at a receive level equal to or greater than the minimum modulation and coding rate sensitivity of –79 dBm shall cause the PHY to set PHY-CCA.indicate(BUSY, {primary, secondary}) for both the primary and secondary channels with a probability per channel > 90% within 4 μs.

A receiver that does not support the reception of HT-GF format PPDUs shall hold the CCA signal busy (PHY_CCA.indicate(BUSY, {primary})) for any valid HT-GF signal in the primary channel at a receive level equal to or greater than –72 dBm when the secondary channel is idle. A receiver that does not support the reception of HT-GF format PPDUs shall hold both the 20 MHz primary channel CCA and the 20 MHz secondary channel CCA busy (PHY_CCA.indicate(BUSY, {primary, secondary})) for any valid 40 MHz HT-GF signal in both the primary and secondary channels at a receive level equal to or greater than –69 dBm.

The receiver shall hold the 20 MHz primary channel CCA signal busy for any signal at or above –62 dBm in the 20 MHz primary channel. This level is 20 dB above the minimum modulation and coding rate sensitivity for a 20 MHz PPDU. When the primary channel is idle, the receiver shall hold the 20 MHz secondary channel CCA busy for any signal at or above –62 dBm in the 20 MHz secondary channel. The receiver shall hold both the 20 MHz primary channel CCA and the 20 MHz secondary channel CCA busy for any signal present in both the primary and secondary channels that is at or above –62 dBm in the primary channel and at or above –62 dBm in the secondary channel.

20.3.21.6 Received channel power indicator (RCPI) measurement

The RCPI is a measure of the received RF power in the selected channel. This parameter shall be a measure by the PHY of the received RF power in the channel measured over the data portion of the received frame. The received power shall be the average of the power in all active receive chains. RCPI shall be a monotonically increasing, logarithmic function of the received power level defined in dBm. The allowed values for the Received Channel Power Indicator (RCPI) parameter shall be an 8 bit value in the range from 0 to 220, with indicated values rounded to the nearest 0.5 dB as follows:

- 0: Power < –110 dBm
- 1: Power = –109.5 dBm
- 2: Power = –109.0 dBm
- And so on up to
- 220: Power > 0 dBm
- 221–254: reserved
- 255: Measurement not available

where

\[
\text{RCPI} = \text{Int}\{(\text{Power in dBm} +110)\times2\} \quad \text{for} \ 0 \ \text{dBm} > \ \text{Power} > –110 \ \text{dBm}
\]  

(20-90)

RCPI shall equal the received RF power within an accuracy of ± 5 dB (95% confidence interval) within the specified dynamic range of the receiver. The received RF power shall be determined assuming a receiver noise equivalent bandwidth equal to the channel width multiplied by 1.1.

20.3.21.7 Reduced interframe space (RIFS)

The receiver shall be able to decode a packet that was transmitted by a STA with a RIFS separation from the previous packet.
20.3.22 PLCP transmit procedure

There are three options for the transmit PLCP procedure. The first two options, for which typical transmit procedures are shown in Figure 20-22 and Figure 20-23, are selected if the FORMAT field of the PHY-TXSTART.request(TXVECTOR) primitive is equal to HT_MF or HT_GF, respectively. These transmit procedures do not describe the operation of optional features, such as LDPC or STBC. The third option is to follow the transmit procedure in Clause 18 or Clause 19 if the FORMAT field is equal to NON_HT. Additionally, if the FORMAT field is equal to NON_HT, CH_BANDWIDTH indicates NON_HT_CBW20, and NON_HT_MODULATION indicates OFDM, follow the transmit procedure in Clause 18. If the FORMAT field is equal to NON_HT, CH_BANDWIDTH indicates NON_HT_CBW20, and NON_HT_MODULATION indicates other than OFDM, follow the transmit procedure in Clause 19. And furthermore, if the FORMAT field is equal to NON_HT and CH_BANDWIDTH indicates NON_HT_CBW40, follow the transmit procedure in Clause 18, except that the signal in Clause 18 is generated simultaneously on each of the upper and lower 20 MHz channels that constitute the 40 MHz channel as defined in 20.3.8 and 20.3.11.12. In all these options, in order to transmit data, the PHY-TXSTART.request primitive shall be enabled so that the PHY entity shall be in the transmit state. Further, the PHY shall be set to operate at the appropriate frequency through station management via the PLME, as specified in 20.4. Other transmit parameters, such as MCS coding types and transmit power, are set via the PHY-SAP with the PHY-TXSTART.request(TXVECTOR) primitive, as described in 20.2.2.

Figure 20-22—PLCP transmit procedure (HT-mixed format PPDU)
A clear channel shall be indicated by a PHY-CCA.indication(IDLE) primitive. Note that under some circumstances, the MAC uses the latest value of the PHY-CCA.indication primitive before issuing the PHY-TXSTART.request primitive. Transmission of the PPDU shall be initiated after receiving the PHY-TXSTART.request(TXVECTOR) primitive. The TXVECTOR elements for the PHY-TXSTART.request primitive are specified in Table 20-1.

The PLCP shall issue the parameters in the following PMD primitives to configure the PHY:
- PMD_TXPWRLVL
- PMD_TX_PARAMETERS

The PLCP shall then issue a PMD_TXSTART.request primitive, and transmission of the PLCP preamble may start if TIME_OF_DEPARTURE_REQUESTED is false, and shall start immediately if TIME_OF_DEPARTURE_REQUESTED is true, based on the parameters passed in the PHY-TXSTART.request primitive. If dot11MgmtOptionTODImplemented and dot11MgmtOptionTODActivated are true or if dot11MgmtOptionTimingMsmtActivated is true and the TXVECTOR parameter TIME_OF_DEPARTURE_REQUESTED is true, then the PLCP shall issue a PHY_TXSTART.confirm(TXSTATUS) primitive to the MAC, forwarding the TIME_OF_DEPARTURE corresponding to the time when the first frame energy is sent by the transmitting port and the TIME_OF_DEPARTURE_ClockRate parameter within the TXSTATUS vector. If dot11MgmtOptionTimingMsmtActivated is true, then the PLCP shall forward the value of TX_START_OF_FRAME_OFFSET in TXSTATUS vector. The data shall then be exchanged between the MAC and the PHY through a series of PHY-DATA.request(DATA) primitives issued by the MAC and PHY-DATA.confirm primitives issued by the PHY. Once PLCP preamble transmission is started, the PHY entity

Figure 20-23—PLCP transmit procedure (HT-greenfield format PPDU)
shall immediately initiate data scrambling and data encoding. The encoding method shall be based on the 
FEC_CODING, CH_BANDWIDTH, and MCS parameter of the TXVECTOR. A modulation rate change, if 
yany, shall be initiated starting with the SERVICE field data, as described in 20.3.2.

The PHY proceeds with PSDU transmission through a series of data octet transfers from the MAC. The 
SERVICE field and PSDU are encoded by the encoder selected by the FEC_CODING, CH_BANDWIDTH, 
and MCS parameters of the TXVECTOR as described in 20.3.3. At the PMD layer, the data octets are sent in 
bit 0–7 order and presented to the PHY through PMD_DATA.request primitives. Transmission can be 
prematurely terminated by the MAC through the primitive PHY-TXEND.request primitive. PHY-TXSTART 
shall be disabled by receiving a PHY-TXSTART.request primitive. Normal termination occurs after the 
transmission of the final bit of the last PSDU octet, according to the number supplied in the LENGTH field.

The packet transmission shall be completed, and the PHY entity shall enter the receive state (i.e., PHY- 
TXSTART shall be disabled). Each PHY-TXEND.request primitive is acknowledged with a PHY-TXEND.confirm primitive from the PHY. If the length of the coded PSDU (C-PSDU) is not an integral 
multiple of the OFDM symbol length, bits shall be stuffed to make the C-PSDU length an integral multiple 
of the OFDM symbol length.

In the PMD, the GI or short GI shall be inserted in every OFDM symbol as a countermeasure against delay 
spread.

In some PPDU formats (as defined in 20.3.2), a signal extension is present. When no signal extension is 
present, the PHY-TXEND.confirm primitive is generated at the end of last symbol of the PPDU. When a 
signal extension is present, the PHY-TXEND.confirm primitive is generated at the end of the signal 
extension.

A typical state machine implementation of the transmit PLCP is provided in Figure 20-24. Requests 
(.request) and confirmations (.confirm) are issued once per state as shown. This state machine does not 
describe the operation of optional features, such as LDPC or STBC.

20.3.23 PLCP receive procedure

Typical PLCP receive procedures are shown in Figure 20-25 and Figure 20-26. The receive procedures 
correspond to HT-mixed format and HT-greenfield format, respectively. A typical state machine 
implementation of the receive PLCP is given in Figure 20-27. These receive procedures and state machine 
do not describe the operation of optional features, such as LDPC or STBC. If the detected format indicates a 
non-HT PPDU format, refer to the receive procedure and state machine in Clause 18 or Clause 19. Further, 
through station management (via the PLME), the PHY is set to the appropriate frequency, as specified in 
20.4. Other receive parameters, such as RSSI and indicated DATARATE, may be accessed via the 
PHY-SAP.

Upon receiving the transmitted PLCP preamble, the PMD_RSSI.indication primitive shall report a receive 
signal strength to the PLCP. This PHY indicates activity to the MAC via the PHY-CCA.indication primitive. 
A PHY-CCA.indication(BUSY, channel-list) primitive shall also be issued as an initial indication of 
reception of a signal. The channel-list parameter of the PHY-CCA.indication primitive is determined as 
follows:

— It is absent when the operating channel width is 20 MHz.
— It is set to {primary} when the operating channel width is 40 MHz and the signal is present only in 
  the primary channel.
— It is set to {secondary} when the operating channel width is 40 MHz and the signal is present only in 
  the secondary channel.
— It is set to {primary, secondary} when the operating channel width is 40 MHz and the signal is 
  present in both the primary and secondary channels.
Figure 20-24—PLCP transmit state machine
The PMD primitive PMD_RSSI is issued to update the RSSI and parameter reported to the MAC.

After the PHY-CCA.indication(BUSY, channel-list) primitive is issued, the PHY entity shall begin receiving the training symbols and searching for SIGNAL and HT-SIG in order to set the length of the data stream, the demodulation type, code type, and the decoding rate. If signal loss occurs before validating L-SIG and/or HT-SIG, the HT PHY shall not generate a PHY-CCA.indication(IDLE) primitive until the received level drops below the CCA sensitivity level (for a missed preamble) specified in 20.3.21.5. If the check of the HT-SIG CRC is not valid, a PHY-RXSTART.indication primitive is not issued. The PHY shall indicate the error condition using a PHY-RXEND.indication(FormatViolation) primitive. The HT PHY shall not generate a PHY-CCA.indication(IDLE) primitive until the received level drops below the CCA sensitivity level (for a missed preamble) specified in 20.3.21.5.

If the PLCP preamble reception is successful and a valid HT-SIG CRC is indicated:

— Upon reception of an HT-mixed format preamble, the HT PHY shall not generate a PHY-CCA.indication(IDLE) primitive for the predicted duration of the transmitted frame, as defined by TXTIME in 20.4.3, for all supported and unsupported modes except Reserved HT-SIG Indication. Reserved HT-SIG Indication is defined in the fourth list item below.
— Upon reception of a GF preamble by an HT STA that does not support GF, the HT PHY shall not generate a PHY-CCA.indication(IDLE) primitive until either the predicted duration of the packet from the contents of the HT-SIG field, as defined by TXTIME in 20.4.3, except Reserved HT-SIG Indication, elapses or until the received level drops below the receiver minimum sensitivity level of BPSK, R=1/2 in Table 20-23 + 10 dB (−72 dBm for 20 MHz, −69 dBm for 40 MHz). Reserved HT-SIG Indication is defined in the fourth list item below.

— Upon reception of a GF preamble by an HT STA that supports GF, the HT PHY shall not generate a PHY-CCA.indication(IDLE) primitive for the predicted duration of the transmitted frame, as defined by TXTIME in 20.4.3, for all supported and unsupported modes except Reserved HT-SIG Indication. Reserved HT-SIG Indication is defined in the fourth list item below.

— If the HT-SIG indicates a Reserved HT-SIG Indication, the HT PHY shall not generate a PHY-CCA.indication(IDLE) primitive until the received level drops below the CCA sensitivity level (minimum modulation and coding rate sensitivity + 20 dB) specified in 20.3.21.5. Reserved HT-SIG Indication is defined as an HT-SIG with MCS field in the range 77–127 or Reserved field = 0 or STBC field = 3 and any other HT-SIG field bit combinations that do not correspond to modes of PHY operation defined in Clause 20.

NOTE—This procedure does not describe the operation of optional features, such as LDPC or STBC.

Figure 20-26—PLCP receive procedure for HT-greenfield format PLCP
Figure 20-27—PLCP receive state machine

NOTE—This state machine does not describe the operation of optional features, such as LDPC or STBC.
Subsequent to an indication of a valid HT-SIG CRC, a PHY-RXSTART.indication(RXVECTOR) primitive shall be issued. If dot11MgmtOptionTimingMsmtActivated is true, the PLCP shall do the following:

- Complete receiving the PLCP header and verify the validity of the PLCP Header.
- If the PLCP header reception is successful (and the SIGNAL field is completely recognizable and supported), a PHY-RXSTART.indication(RXVECTOR) shall be issued and RX_START_OF_FRAME_OFFSET parameter within the RXVECTOR shall be forwarded (see 20.2.2).

NOTE—The RX_START_OF_FRAME_OFFSET value is used as described in 6.3.57 in order to estimate when the start of the preamble for the incoming frame was detected on the medium at the receive antenna port.

The RXVECTOR associated with this primitive includes the parameters specified in Table 20-1. Upon reception of a GF preamble by an HT STA that does not support GF, the FORMAT field of RXVECTOR is equal to HT_GF, the remaining fields may be empty, and the PHY shall indicate the error condition using a PHY-RXEND.indication(FormatViolation) primitive. If the HT-SIG indicates an unsupported mode or Reserved HT-SIG Indication, the PHY shall indicate the error condition using a PHY-RXEND.indication(UnsupportedRate) primitive.

Following training and SIGNAL fields, the coded PSDU (C-PSDU) (which comprises the coded PLCP SERVICE field and scrambled and coded PSDU) shall be received. If signal loss occurs during reception prior to completion of the PSDU reception, the error condition shall be reported to the MAC using a PHY-RXEND.indication(CarrierLost) primitive. After waiting for the intended end of the PSDU, if no signal extension is present (as defined in 20.3.2), the PHY shall generate a PHY-CCA.indication(IDLE) primitive and return to RX IDLE state. Otherwise, the receiver waits for the duration of the signal extension before returning to the RX IDLE state.

The received PSDU bits are assembled into octets, decoded, and presented to the MAC using a series of PHY-DATA.indication(DATA) primitive exchanges. The number of PSDU octets is indicated in the HT Length field of the HT-SIG. The PHY shall proceed with PSDU reception. After the reception of the final bit of the last PSDU octet and possible tail and padding bits, the receiver shall be returned to the RX IDLE state if no signal extension is present (as defined in 20.3.2), as shown in Figure 20-27. Otherwise, the receiver waits for the duration of the signal extension before returning to the RX IDLE state. A PHY-RXEND.indication(NoError) primitive shall be issued on entry to the RX IDLE state.

While in the Signal Extension state, if the receiver detects a CS/CCA event, it issues an RXEND.indication primitive (with the RXERROR parameter set to NoError or CarrierLost, depending on whether a carrier lost event occurred during the reception of the PPDU), leaves the Signal Extension state, and enters the Detect SIG state. This sequence occurs when signal-extended PPDUs are transmitted while separated by a RIFS.

If the binary convolutional code is used, any data received after the indicated data length are considered pad bits (to fill out an OFDM symbol) and should be discarded.

20.4 HT PLME

20.4.1 PLME_SAP sublayer management primitives

Table 20-24 lists the MIB attributes that may be accessed by the PHY entities and the intralayer of higher level LMEs. These attributes are accessed via the PLME-GET, PLME-SET, PLME-RESET, and PLME-CHARACTERISTICS primitives defined in 10.4.
20.4.2 PHY MIB

HT PHY MIB attributes are defined in Annex C with specific values defined in Table 20-24. The “Operational semantics” column in Table 20-24 contains two types: static and dynamic.

— Static MIB attributes are fixed and cannot be modified for a given PHY implementation.
— Dynamic MIB attributes are interpreted according to the MAX-ACCESS field of the MIB attribute. When MAX-ACCESS is equal to read-only, the MIB attribute value may be updated by the PLME and read from the MIB attribute by management entities. When MAX-ACCESS is equal to read-write, the MIB attribute may be read and written by management entities.

20.4.3 TXTIME calculation

The value of the TXTIME parameter returned by the PLME-TXTIME.confirm primitive or calculated for
the PLCP receive procedure shall be calculated for HT-mixed format according to the Equation (20-91) and
Equation (20-92) for short and regular GI, respectively, and for HT-greenfield format according to
Equation (20-93) and Equation (20-94) for short and regular GI, respectively:

\[
TXTIME = T_{LEG\_PREAMBLE} + T_{L\_SIG} + T_{HT\_PREAMBLE} + T_{HT\_SIG} + T_{SYM} \times \text{Ceiling}\left(\frac{T_{SYS} \times N_{SYM}}{T_{SYM}}\right) + \text{SignalExtension} \tag{20-91}
\]

\[
TXTIME = T_{LEG\_PREAMBLE} + T_{L\_SIG} + T_{HT\_PREAMBLE} + T_{HT\_SIG} + T_{SYM} \times N_{SYM} + \text{SignalExtension} \tag{20-92}
\]

\[
TXTIME = T_{GF\_HT\_PREAMBLE} + T_{HT\_SIG} + T_{SYS} \times N_{SYM} + \text{SignalExtension} \tag{20-93}
\]

\[
TXTIME = T_{GF\_HT\_PREAMBLE} + T_{HT\_SIG} + T_{SYM} \times N_{SYM} + \text{SignalExtension} \tag{20-94}
\]

where

- \(T_{LEG\_PREAMBLE}\) = \(T_{L\_STF} + T_{L\_LTF}\) is the duration of the non-HT preamble
- \(T_{HT\_PREAMBLE}\) is the duration of the HT preamble in HT-mixed format, given by \(T_{HT\_STF} + T_{HT\_LTF1} + (N_{LTF} - 1)T_{HT\_LTFs}\)
- \(T_{GF\_HT\_PREAMBLE}\) is the duration of the preamble in HT-greenfield format, given by \(T_{HT\_GF\_STF} + T_{HT\_LTF1} + (N_{LTF} - 1)T_{HT\_LTFs}\)
- \(T_{SYS}, T_{SYS}, T_{HT\_SIG}, T_{L\_STF}, T_{HT\_STF}, T_{HT\_GF\_STF}, T_{L\_LTF}, T_{HT\_LTF1}\) and \(T_{HT\_LTFs}\) are defined in Table 20-6
- \(\text{SignalExtension}\) is 0 µs when TXVECTOR parameter NO_SIG_EXTN is true and is the duration of
  signal extension as defined by aSignalExtension in Table 20-5 when TXVECTOR parameter NO_SIG_EXTN is false
- \(N_{LTF}\) is defined in Equation (20-22)
- \(N_{SYM}\) is defined in Equation (20-32) for BCC and Equation (20-41) for LDPC

For non-HT modes of operation, refer to Clause 18 and Clause 19 for TXTIME calculations, except that
frames transmitted with a value of NON_HT_DUP_OFDM for the TXVECTOR parameter
NON_HT_MODULATION shall use Equation (19-6) for TXTIME calculation.
20.4.4 PHY characteristics

The static HT PHY characteristics, provided through the PLME-CHARACTERISTICS service primitive, shall be as shown in Table 20-25. The definitions for these characteristics are given in 10.4.

20.5 HT PMD sublayer

20.5.1 Scope and field of application

The PMD services provided to the PLCP for the High Throughput (HT) PHY are described in 20.5. Also defined in this subclause are the functional, electrical, and RF characteristics required for interoperability of implementations conforming to this specification. The relationship of this specification to the entire HT PHY is shown in Figure 20-28.

20.5.2 Overview of service

The HT PMD sublayer accepts PLCP sublayer service primitives and provides the actual means by which data are transmitted or received from the medium. The combined function of the HT PMD sublayer primitives and parameters for the receive function results in a data stream, timing information, and associated receive signal parameters being delivered to the PLCP sublayer. A similar functionality is provided for data transmission.
20.5.3 Overview of interactions

The primitives provided by the HT PMD fall into two basic categories:
   a) Service primitives that support PLCP peer-to-peer interactions
   b) Service primitives that have local significance and support sublayer-to-sublayer interactions

20.5.4 Basic service and options

20.5.4.1 Status of service primitives

All of the service primitives described in 20.5.4 are mandatory, unless otherwise specified.

20.5.4.2 PMD_SAP peer-to-peer service primitives

Table 20-26 indicates the primitives for peer-to-peer interactions.

20.5.5 PMD_SAP detailed service specification

20.5.5.1 Introduction to PMD_SAP service specification

Subclauses 20.5.5.2 through 20.5.5.13 describe the services provided by each PMD primitive.

20.5.5.2 PMD_DATA.request

20.5.5.2.1 Function

This primitive defines the transfer of data from the PLCP sublayer to the PMD entity.

20.5.5.2.2 Semantics of the service primitive

This primitive shall provide the following parameter:

\[
\text{PMD\_DATA.request( TXD\_UNIT )}
\]

The TXD UNIT parameter shall be the \( n \)-bit combination of 0 and 1 for one symbol of OFDM modulation. If the length of a coded PSDU (C-PSDU) is shorter than \( n \) bits, 0 bits are added to form an OFDM symbol. This parameter represents a single block of data that, in turn, shall be used by the PHY to be encoded into an OFDM transmitted symbol.

20.5.5.2.3 When generated

This primitive shall be generated by the PLCP sublayer to request transmission of one OFDM symbol.

20.5.5.2.4 Effect of receipt

The PMD performs transmission of the data.

20.5.5.3 PMD_DATA.indication

20.5.5.3.1 Function

This primitive defines the transfer of data from the PMD entity to the PLCP sublayer.
20.5.5.3.2 Semantics of the service primitive

This primitive shall provide the following parameter:

\[ \text{PMD\textunderscore DATA\textunderscore indication(RXD\_UNIT)} \]

The RXD\_UNIT parameter shall be 0 or 1 and shall represent either a SIGNAL field bit or a data field bit after the decoding of the FEC by the PMD entity.

20.5.5.3.3 When generated

This primitive, generated by the PMD entity, forwards received data to the PLCP sublayer.

20.5.5.3.4 Effect of receipt

The PLCP sublayer decodes the bits that it receives from the PMD and either interprets them as part of its own signaling or passes them to the MAC sublayer as part of the PSDU after any necessary additional processing (e.g., descrambling).

20.5.5.4 PMD\_TXSTART\_request

20.5.5.4.1 Function

This primitive, generated by the PHY PLCP sublayer, initiates PPDU transmission by the PMD layer.

20.5.5.4.2 Semantics of the service primitive

This primitive has no parameters.

20.5.5.4.3 When generated

This primitive shall be generated by the PLCP sublayer to initiate the PMD layer transmission of the PPDU. The PHY\_TXSTART\_request primitive shall be provided to the PLCP sublayer prior to issuing the PMD\_TXSTART command.

20.5.5.4.4 Effect of receipt

PMD\_TXSTART initiates transmission of a PPDU by the PMD sublayer.

20.5.5.5 PMD\_TXEND\_request

20.5.5.5.1 Function

This primitive, generated by the PHY PLCP sublayer, ends PPDU transmission by the PMD layer.

20.5.5.5.2 Semantics of the service primitive

This primitive has no parameters.

20.5.5.5.3 When generated

This primitive shall be generated by the PLCP sublayer to terminate the PMD layer transmission of the PPDU.
20.5.5.5.4 Effect of receipt

PMD_TXEND terminates transmission of a PPDU by the PMD sublayer.

20.5.5.6 PMD_TXEND.confirm

20.5.5.6.1 Function

This primitive, generated by the PMD entity, indicates the end of PPDU transmission by the PMD layer. It is generated at the 4 µs boundary following the trailing boundary of the last symbol transmitted.

20.5.5.6.2 Semantics of the service primitive

This primitive has no parameters.

20.5.5.6.3 When generated

This primitive shall be generated by the PMD entity at the 4 µs boundary following the trailing boundary of the last symbol transmitted.

20.5.5.6.4 Effect of receipt

The PLCP sublayer determines that transmission of the last symbol of the PPDU is complete. This completion is used as a timing reference in the PLCP state machines. See 20.3.22.

20.5.5.7 PMD_TXPWRLVL.request

20.5.5.7.1 Function

This primitive, generated by the PHY PLCP sublayer, selects the power level used by the PHY for transmission.

20.5.5.7.2 Semantics of the service primitive

This primitive shall provide the following parameter:

```
PMD_TXPWRLVL.request(
    TXPWR_LEVEL
)
```

TXPWR_LEVEL selects which of the transmit power levels should be used for the current packet transmission. The number of available power levels shall be determined by the MIB parameter aNumberSupportedPowerLevels. See 20.3.20.3 for further information on the OFDM PHY power level control capabilities.

20.5.5.7.3 When generated

This primitive shall be generated by the PLCP sublayer to select a specific transmit power. This primitive shall be applied prior to setting PMD_TXSTART into the transmit state.

20.5.5.7.4 Effect of receipt

PMD_TXPWRLVL immediately sets the transmit power level to the level given by TXPWR_LEVEL.
20.5.5.8 PMD_RSSI.indication

20.5.5.8.1 Function

This primitive, generated by the PMD sublayer, provides the receive signal strength to the PLCP and MAC entity.

20.5.5.8.2 Semantics of the service primitive

This primitive shall provide the following parameter:

```
PMD_RSSI.indication( RSSI )
```

The RSSI shall be a measure of the RF energy received by the HT PHY. RSSI indications of up to 8 bits (256 levels) are supported.

20.5.5.8.3 When generated

This primitive shall be generated by the PMD after the reception of the HT training fields.

20.5.5.8.4 Effect of receipt

This parameter shall be provided to the PLCP layer for information only. The RSSI may be used as part of a CCA scheme.

20.5.5.9 PMD_RCPI.indication

20.5.5.9.1 Function

This primitive, generated by the PMD sublayer, provides the received channel power indicator to the PLCP and MAC entity.

20.5.5.9.2 Semantics of the service primitive

The primitive shall provide the following parameter:

```
PMD_RCPI.indication( RCPI )
```

The RCPI is a measure of the channel power received by the OFDM PHY. RCPI measurement and parameter values are defined in 20.3.21.6.

20.5.5.9.3 When generated

This primitive shall be generated by the PMD when the OFDM PHY is in the receive state. It is generated at the end of the last received symbol.

20.5.5.9.4 Effect of receipt

This parameter shall be provided to the PLCP layer for information only. The RCPI may be used in conjunction with RSSI to measure input signal quality.
20.5.5.10 PMD_TX_PARAMETERS.request

20.5.5.10.1 Function

This primitive, generated by the PHY PLCP sublayer, selects the related parameters used by the PHY for transmission.

20.5.5.10.2 Semantics of the service primitive

This primitive shall provide the following parameters:

PMD_TX_PARAMETERS.request(
  MCS,
  CH_BANDWIDTH,
  CH_OFFSET,
  STBC,
  GI_TYPE,
  ANTENNA_SET,
  FEC_CODING,
  PMD_EXPANSIONS_MAT,
  PMD_EXPANSIONS_MAT_TYPE
)

20.5.5.10.3 When generated

This primitive shall be generated by the PLCP sublayer to select a specific transmit parameter. This primitive shall be applied prior to setting PMD_TXSTART into the transmit state.

20.5.5.10.4 Effect of receipt

PMD_TX_PARAMETERS immediately sets the transmit parameters. The receipt of these parameters selects the values that shall be used for all subsequent PPDU transmissions.

20.5.5.11 PMD_CBW_OFFSET.indication

20.5.5.11.1 Function

This primitive, generated by the PMD sublayer, provides the bandwidth and channel offset of the received frame to the PLCP and MAC entity.

20.5.5.11.2 Semantics of the service primitive

This primitive shall provide the following parameters:

PMD_CBW_OFFSET.indication(
  CH_BANDWIDTH,
  CH_OFFSET
)

CH_BANDWIDTH represents channel width (20 MHz or 40 MHz) in which the data are transmitted and the transmission format (non-HT duplicate or MCS 32). CH_OFFSET indicates in a 20 MHz bandwidth, in a 20 MHz subchannel of the 40 MHz channel (upper or lower), or in the entire 40 MHz channel.
20.5.5.11.3 When generated

This primitive shall be generated by the PMD when the OFDM PHY is in the receive state. It shall be available continuously to the PLCP that, in turn, shall provide the parameter to the MAC entity.

20.5.5.11.4 Effect of receipt

The PLCP sublayer passes the data to the MAC sublayer as part of the RXVECTOR.

20.5.5.12 PMD_CHAN_MAT.indication

20.5.5.12.1 Function

This primitive, generated by the PMD sublayer, provides the channel response matrices to the PLCP and MAC entity.

20.5.5.12.2 Semantics of the service primitive

This primitive shall provide the following parameter:

\[
\text{PMD\_CHAN\_MAT.\_indication}(
\quad \text{CHAN\_MAT}
\)
\]

The CHAN_MAT parameter contains the channel response matrices that were measured during the reception of the current frame.

20.5.5.12.3 When generated

This primitive shall be generated by the PMD when the OFDM PHY is in the receive state. It shall be available continuously to the PLCP that, in turn, shall provide the parameter to the MAC entity.

20.5.5.12.4 Effect of receipt

The PLCP sublayer passes the data to the MAC sublayer as part of the RXVECTOR.

20.5.5.13 PMD_FORMAT.indication

20.5.5.13.1 Function

This primitive, generated by the PMD sublayer, provides the format of the received frame to the PLCP and MAC entity.

20.5.5.13.2 Semantics of the service primitive

This primitive shall provide the following parameter:

\[
\text{PMD\_FORMAT.\_indication}(
\quad \text{FORMAT}
\)
\]

The format indicates one of the PPDU formats: non-HT, HT-mixed format, or HT-greenfield format.

20.5.5.13.3 When generated

This primitive shall be generated by the PMD after the reception of the HT training fields.
20.5.5.13.4 Effect of receipt

The PLCP sublayer passes the data to the MAC sublayer as part of the RXVECTOR.

20.6 Parameters for HT MCSs

Table 20-29 defines the symbols used in the rate-dependent parameter tables.

<table>
<thead>
<tr>
<th>Symbol</th>

Annex B

(normative)

Protocol Implementation Conformance Statement (PICS) proforma

B.1 Introduction

The supplier of a protocol implementation that is claimed to conform to IEEE Std 802.11-2012 shall complete the following protocol implementation conformance statement (PICS) proforma.

A completed PICS proforma is the PICS for the implementation in question. The PICS is a statement of which capabilities and options of the protocol have been implemented. This annex may not be compatible with operation in any Regulatory Domain or describe combinations of usable features in any Regulatory Domain. The PICS has a number of uses, including use:

a) By the protocol implementer, as a checklist to reduce the risk of failure to conform to the standard through oversight;

b) By the supplier and acquirer, or potential acquirer, of the implementation, as a detailed indication of the capabilities of the implementation, stated relative to the common basis for understanding provided by the standard PICS proforma;

c) By the user, or potential user, of the implementation, as a basis for initially checking the possibility of interworking with another implementation (note that, while interworking is not guaranteed, failure to interwork can often be predicted from incompatible PICS proformas);

d) By a protocol tester, as the basis for selecting appropriate tests against which to assess the claim for conformance of the implementation.

B.2 Abbreviations and special symbols

B.2.1 Symbols for Status column

M mandatory
O optional
O.<n> optional, but support of at least one of the group of options labeled by the same numeral <n> is required
pred: conditional symbol, including predicate identification

B.2.2 General abbreviations for Item and Support columns

N/A not applicable
AD address function capability
CF implementation under test (IUT) configuration
DS direct sequence
DSE dynamic station enablement
ERP extended rate physical layer (PHY)
FH frequency hopping
FR medium access control (MAC) frame capability
FS frame sequence capability
B.3 Instructions for completing the PICS proforma

B.3.1 General structure of the PICS proforma

The first parts of the PICS proforma, Implementation identification and Protocol summary, are to be completed as indicated with the information necessary to identify fully both the supplier and the implementation.

The main part of the PICS proforma is a fixed questionnaire, divided into subclauses, each containing a number of individual items. Answers to the questionnaire items are to be provided in the rightmost column, either by simply marking an answer to indicate a restricted choice (usually Yes or No) or by entering a value or a set or a range of values. (Note that there are some items where two or more choices from a set of possible answers may apply. All relevant choices are to be marked in these cases.)

Each item is identified by an item reference in the first column. The second column contains the question to be answered. The third column contains the reference or references to the material that specifies the item in the main body of this standard. The remaining columns record the status of each item, i.e., whether support is mandatory, optional, or conditional, and provide the space for the answers (see also B.3.4). Marking an item as supported is to be interpreted as a statement that all relevant requirements of the subclauses and normative annexes, cited in the References column for the item, are met by the implementation.

A supplier may also provide, or be required to provide, further information, categorized as either Additional Information or Exception Information. When present, each kind of further information is to be provided in a further subclause of items labeled A<|I> or X<|I>, respectively, for cross-referencing purposes, where <|I> is any unambiguous identification for the item (e.g., simply a numeral). There are no other restrictions on its format or presentation.

A completed PICS proforma, including any Additional Information and Exception Information, is the PICS for the implementation in question.
NOTE—Where an implementation is capable of being configured in more than one way, a single PICS might be able to describe all such configurations. However, the supplier has the choice of providing more than one PICS, each covering some subset of the implementation’s capabilities, if this makes for easier and clearer presentation of the information.

B.3.2 Additional information

Items of Additional Information allow a supplier to provide further information intended to assist in the interpretation of the PICS. It is not intended or expected that a large quantity of information will be supplied, and a PICS can be considered complete without any such information. Examples of such Additional Information might be an outline of the ways in which an (single) implementation can be set up to operate in a variety of environments and configurations, or information about aspects of the implementation that are outside the scope of this standard but have a bearing upon the answers to some items.

References to items of Additional Information may be entered next to any answer in the questionnaire, and may be included in items of Exception Information.

B.3.3 Exception information

It may happen occasionally that a supplier wishes to answer an item with mandatory status (after any conditions have been applied) in a way that conflicts with the indicated requirement. No preprinted answer is found in the Support column for this. Instead, the supplier shall write the missing answer into the Support column, together with an X<item> reference to an item of Exception Information, and shall provide the appropriate rationale in the Exception Information item itself.

An implementation for which an Exception Information item is required in this way does not conform to this standard.

NOTE—A possible reason for the situation described above is that a defect in this standard has been reported, a correction for which is expected to change the requirement not met by the implementation.

B.3.4 Conditional status

The PICS proforma contains a number of conditional items. These are items for which both the applicability of the item itself, and its status if it does apply, mandatory or optional, are dependent upon whether certain other items are supported.

Where a group of items is subject to the same condition for applicability, a separate preliminary question about the condition appears at the head of the group, with an instruction to skip to a later point in the questionnaire if the N/A answer is selected. Otherwise, individual conditional items are indicated by a conditional symbol in the Status column.

A conditional symbol is of the form “<pred>:<S>”, where “<pred>” is a predicate as described below, and “<S>” is one of the status symbols M or O.

If the value of the predicate is true, the conditional item is applicable, and its status is given by S: the support column is to be completed in the usual way. Otherwise, the conditional item is not relevant and the N/A answer is to be marked.

A predicate is one of the following:

a) An item-reference for an item in the PICS proforma: the value of the predicate is true if the item is marked as supported, and is false otherwise.
b) An expression constructed by combining item-references using the boolean operators “not,” “OR,” and “AND” (synonym “&”), with or without the use of parenthetical groupings: the value of the predicate is true if the expression evaluates to true and is false otherwise.

Each item referenced in a predicate, or in a preliminary question for grouped conditional items, is indicated by an asterisk in the Item column.

**B.4 PICS proforma—IEEE Std 802.11-2012**

**B.4.1 Implementation identification**

<table>
<thead>
<tr>
<th>Supplier</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Contact point for queries about the PICS</td>
<td></td>
</tr>
<tr>
<td>Implementation Name(s) and Version(s)</td>
<td></td>
</tr>
<tr>
<td>Other information necessary for full identification, e.g., name(s) and version(s) of the machines and/or operating systems(s), system names</td>
<td></td>
</tr>
</tbody>
</table>

**NOTE 1**—Only the first three items are required for all implementations. Other information may be completed as appropriate in meeting the requirement for full identification.

**NOTE 2**—The terms Name and Version need to be interpreted appropriately to correspond with a supplier’s terminology (e.g., Type, Series, Model).

Annex C
(normative)

ASN.1 encoding of the MAC and PHY MIB

C.1 General

The MIB for the current revision of IEEE STD 802.11 is available online at the following URL:

C.2 Guidelines for 802.11 MIB Authors/Editors

The MIB may be compiled using the "smitools" package from the Institute of Operating Systems and Computer Networks at the Technical University of Braunschweig, Germany. These tools may be accessed online using the following URL: http://www.ibr.cs.tu-bs.de/bin/smitools.cgi.

Using this tool, the MIB should compile without generating warnings of severity 3 or lower.

Specific points that authors and editors should pay attention to:
— The MIB should compile as specified above prior to submission to IEEE-SA RevCom.
— Use only the 7-bit character-set. In particular, use only straight single and double quotes.
— Do not use symbols such as µ in units, instead spell out the units fully, i.e., "microseconds."
— Pay attention to IETF recommendations on object types.
— When adding a lot of new objects, consider adding a new module.
— Consider seeking advice from an IETF MIB Doctor when creating significant new material. The IEEE has an arrangement with the IETF whereby the IEEE may ask for a MIB Advisor from the IETF MIB Doctors.
— When an object is deprecated, add a line to the Description indicating why (IETF convention).

C.3 MIB Detail

DESCRIPTION
"The MIB module for IEEE 802.11 entities.
iso(1).member-body(2).us(840).ieee802dot11(10036)"
REVISION "201203300000Z"
DESCRIPTION "Draft Revision MB of the 802.11 Standard.

Note that not all objects within this MIB are referenced by a group, and
not all groups are referenced by a MODULE-COMPLIANCE statement. Some
existing groups and the dot11Compliance MODULE-COMPLIANCE have been modi-
fied since the previous revision of this standard.

Implementations should not claim compliance to dot11Compliance."

MAX-ACCESS read-write  
STATUS current  
DESCRIPTION  
  "This is a control variable. 
  It is written by the SME or external management entity. 
  Changes take effect for the next MLME-START.request primitive. 

  The purpose of dot11StationID is to allow a manager to identify a station 
  for its own purposes. This attribute provides for that eventuality while 
  keeping the true MAC address independent. Its syntax is MAC address, and 
  the default value is the station's assigned, unique MAC address."  
::= { dot11StationConfigEntry 1 }

dot11MediumOccupancyLimit OBJECT-TYPE  
SYNTAX Unsigned32 (0..1000)  
MAX-ACCESS read-write  
STATUS current  
DESCRIPTION  
  "This is a control variable. 
  It is written by an external management entity. 
  Changes take effect as soon as practical in the implementation. 

  This attribute indicates the maximum amount of time, in TU, that a point 
  coordinator (PC) may control the usage of the wireless medium (WM) without 
  relinquishing control for long enough to allow at least one instance of 
  DCF access to the medium. The maximum value of this variable is 1000."  
DEFVAL { 100 }

dot11DesiredSSID OBJECT-TYPE
SYNTAX OCTET STRING (SIZE(0..32))
MAX-ACCESS read-write
STATUS current
DESCRIPTION

"This is a control variable.
It is written by an external management entity.
Changes take effect for the next MLME-SCAN.request primitive.

This attribute reflects the Service Set ID (SSID) used in the SSID parameter of the most recent MLME-SCAN.request primitive. This value may be
modified by an external management entity and used by the local SME to make decisions about the Scanning process."

::= { dot11StationConfigEntry 9 }

dot11DesiredBSSType OBJECT-TYPE
SYNTAX INTEGER { infrastructure(1), independent(2), any(3) }
MAX-ACCESS read-write
STATUS current
DESCRIPTION
"This is a control variable. It is written by an external management entity. Changes take effect for the next MLME-SCAN.request primitive.

This attribute specifies the type of BSS the station uses when scanning for a BSS with which to synchronize. This value is used to filter Probe Response frames and Beacon frames. When equal to infrastructure, the station synchronizes only with a BSS in which the Capability Information field has the ESS subfield equal to 1. When equal to independent, the station synchronizes only with a BSS whose Capability Information field has the IBSS subfield equal to 1. When equal to any, the station may synchronize to either type of BSS."

::= { dot11StationConfigEntry 10 }

dot11OperationalRateSet OBJECT-TYPE
SYNTAX OCTET STRING (SIZE(1..126))
MAX-ACCESS read-only
STATUS current
DESCRIPTION
"This is a status variable. It is written by the SME when joining or establishing a BSS.

This attribute specifies the set of non-HT data rates at which the station may transmit data. The attribute that specifies the set of HT data rates is dot11HTOperationalMCSSet. Each octet contains a value representing a rate. Each rate is within the range from 2 to 127, corresponding to data rates in increments of 500 kbit/s from 1 Mb/s to 63.5 Mb/s, and is supported (as indicated in the supported rates table) for receiving data. This value is reported in transmitted Beacon, Probe Request, Probe Response, Association Request, Association Response, Reassociation Request, and Reassociation Response frames, and is used to determine whether a BSS with which the station desires to synchronize is suitable. It is also used when starting a BSS, as specified in 6.3.4."

SYNTAX DisplayString
MAX-ACCESS read-write
STATUS current
DESCRIPTION
"This is a control variable.
It is written by an external management entity.
Changes take effect as soon as practical in the implementation.

The PSK, for when RSNA in PSK mode is the selected AKM suite, is configure
by dot11RSNAConfigPSKValue.

An alternative manner of setting the PSK uses the password-to-key algorithm defined in M.4. This variable provides a means to enter a pass-
phrase. When this object is written, the RSNA entity uses the password-to-
key algorithm specified in M.4 to derive a preshared and populate dot11RSNAConfigPSKValue with this key.
This object is logically write-only. Reading this variable returns unsuc-
cessful status or null or 0."

"This is a control variable.
It is written by an external management entity.
Changes take effect as soon as practical in the implementation.

When this object is true, this indicates that fast BSS transition (FT) is enabled in this entity. The entity advertises the FT-related elements in its Beacon and Probe Response frames. This object requires that dot11FastBSSTransitionImplemented also be equal to true."
 ::= { dot11FastBSSTransitionConfigEntry 1 }

dot11FTMobilityDomainID OBJECT-TYPE
SYNTAX OCTET STRING (SIZE(2))
MAX-ACCESS read-write
STATUS current
DESCRIPTION
"This is a control variable.
It is written by an external management entity.
Changes take effect as soon as practical in the implementation.

This attribute specifies the Mobility Domain identifier (MDID) of this entity.

The MDID is used to indicate a group of APs, within an ESS, between which a STA can use fast BSS transition services. Fast BSS transitions are allowed only between APs that have the same MDID and are within the same ESS. They are not allowed between APs with different MDIDs or in different ESSs."
Since fast BSS transition services are defined only within the scope of an ESS, there is no requirement that MDIDs be unique across ESSs.

STATUS current
DESCRIPTION
"An entry in the dot11WirelessMgmtOptionsTable. For all Wireless Management features, an Activated MIB variable is used to activate/enable or deactivate/disable the corresponding feature. An Implemented MIB variable is used for an optional feature to indicate whether the feature is implemented. A mandatory feature does not have a corresponding Implemented MIB variable. It is possible for there to be multiple IEEE 802.11 interfaces on one agent, each with its unique MAC address. The relationship between an IEEE 802.11 interface and an interface in the context of the Internet-standard MIB is one-to-one. As such, the value of an ifIndex object instance can be directly used to identify corresponding instances of the objects defined herein. ifIndex - Each IEEE 802.11 interface is represented by an ifEntry. Interface tables in this MIB module are indexed by ifIndex."

"Group contains the current list of WIRELESS Management reports that have
been received by the MLME. The report tables shall be maintained as FIFO
to preserve freshness, thus the rows in this table can be deleted for mem-
ory constraints or other implementation constraints determined by the ven-
dor.
New rows shall have different RprtIndex values than those deleted within
the range limitation of the index. One easy way is to monotonically
increase the EventIndex for new reports being written in the table."

-- ********************************************************************
-- * End of dot11WirelessMGTEvent TABLE
-- ********************************************************************
**IEEE 802.11 RM and WNM Interface MIB**

---

The primary interface to the Radio Measurements and Wireless Network Management functions is meant to be real-time information obtained through the request/response mechanisms of RM and WNM. A secondary interface to the measurements and management functions is through retention of information in this MIB. Non-SNMP requests or wireless interfaces in the operating systems. SNMP requests for information are obtained via SNMP SETs and GETs (see [B24]).

---

**dot11RMRequest and dot11RMReport Usage**

---

The `dot11RMRequest` and `dot11RMReport` portions of the RM MIB provide access to the Radio Measurement service. By performing SET operations on the various `dot11RMRequest` MIB objects, radio measurements may be initiated directly on the local STA or on any peer station within the same BSS. Subsequently, by performing GET operations on the various `dot11RMReport` MIB objects the results of the requested measurements may be retrieved.

---

In the diagram below, a radio measurement could be initiated for STA x by performing a MIB.set operation on the RM MIB of STA x and specifying the MAC address of STA x in `dot11RMrgstTargetAdd`. Additionally, it is possible to have STA x request a measurement from STA y by performing a MIB.set operation on the SME MIB of STA x and specifying the MAC address of STA y in `dot11RMrgstTargetAdd`. In both cases the result of the measurements can be retrieved by performing a MIB.get operation on the RM MIB of STA x upon completion of the measurement.

---

Each STA maintains a single `dot11RMRequestTable` in the SME MIB used to initiate RM Measurement Requests. Each `dot11RMRequestEntry` in the table represents an individual Measurement Request that makes up a complete Measurement Request frame. Multiple Measurement Requests may be concatenated into a single...
-- * Measurement Request frame by setting the same
-- * dot11RMRequestToken value into multiple dot11RMRequestEntries.
-- *
-- * Each row, dot11RMRequestEntry, of the dot11RMRequestTable
-- * provides read-create access for the initiation of a measurement
-- * request. The dot11RMRequestNextIndex object can be used to
-- * determine which is the next available row. Each row corresponding to
-- * one measurement in the sequence is created with a dot11RMRequestRowStatus
-- * equal to notInService. Once the dot11RMRequestEntry(s) have been
-- * created for a desired measurement sequence the corresponding
-- * dot11RMRequestRowStatus(s) objects are set to active to indicate that
-- * the SME can trigger the appropriate MLME primitives. Upon processing
-- * the request, the SME returns the corresponding dot11RMRequestRowStatus(s)
-- * object to notInService and are now available for additional
-- * measurement requests.
-- *
-- * After a radio measurement is complete the RM populates the RMReport
-- * objects with the results of the measurement. Each STA maintains a set
-- * of RMReport tables, one corresponding to each measurement type. The
-- * results of the entire measurement sequence are spread across the tables
-- * based on the type of measurements requested. Each xxxReportEntry
-- * within a xxxReportTable contains a xxxRprtRqstToken that corresponds
-- * to the original dot11RMRequestToken in the measurement request. So the
-- * results of the measurement can be collected by searching the appropriate
-- * xxxReportTables and retrieve any reports with the matching request
-- * token.
-- *
-- * Similar structures and mechanisms are used for WNM
-- * Request and Reports. The WNM MIB definitions follow the RM MIB definitions
-- * in this Annex.

dot11RMRequestNextIndex OBJECT-TYPE
SYNTAX Unsigned32(0..65535)
MAX-ACCESS read-only
STATUS current
DESCRIPTION
"This is a status variable.
It is written by the SME when able to accept a new request.

Identifies a hint for the next value of dot11RMRequestIndex to be used in a
row creation attempt for dot11RMRequestTable. If no new rows can be cre-
ated for some reason, such as memory, processing requirements, etc., the
SME sets this attribute to 0. It updates this attribute to a proper value
other than 0 as soon as it is capable of receiving new measurement
requests. The nextIndex is not necessarily sequential nor monotonically
increasing."
::= { dot11RMRequest 1 }

dot11RMRequestTable OBJECT-TYPE
SYNTAX SEQUENCE OF Dot11RMRequestEntry
MAX-ACCESS not-accessible
STATUS current
DESCRIPTION
"This group contains the current list of requests for RM reports to be
issued and have been issued until removed. A network manager adds a RM
request by creating a row with createAndWait row status and then filling
in the request parameters/attributes. The request becomes active to be
issued when the row status is set to Active. The columnar objects or
attributes other than the rowStatus are not written if the rowStatus is
Active. The request rows can be deleted, if commanded by a network manager
via changing the value of dot11RMrqstRowStatus to Destroy. This may leave
orphaned rows if a manager crashes and forgets which rows are being used
by it. One recommended way to manage orphaned or finished rows is to
delete rows if their dot11RMrqstRowStatus remains other than Active for
longer than a period (recommend at least 5 minutes, IETF RFC 2579). Or
another recommended way is to delete older rows as needed based on their
dot11RMrqstTimeStamp values. This can be done by the agent as well as the
manager."

"Identifies the next available index for managing the neighbor report
table. If this attribute is 0, it indicates that the neighbor report fea-
ture is not configurable via SNMP, or the table is full and new rows can-
not be accepted."
 ::= { dot11RMConfig 2 }

dot11RMNeighborReportTable OBJECT-TYPE
SYNTAX SEQUENCE OF Dot11RMNeighborReportEntry
MAX-ACCESS not-accessible
STATUS current
DESCRIPTION
"This table contains pertinent information on a collection of BSSID's that
are candidates to which STAs can roam. The rows are created using create-
AndWait method and fill in the attributes. When the rowStatus is set to
active, the row can be included in Neighbor Report elements. If there is
an error, the rowStatus is set to notReady by SME. Since this table con-
tains all Neighbor Report element entries for all interfaces enabled with
the neighbor report feature, it is possible to have too many entries for
one interface, while still remaining under the MaxTableSize. In that situ-
ation, SME includes neighbor report entries only with lower
dot11RMNeighborReportIFIndex up to the maximum possible number of entries
for a particular interface identified by ifIndex. SME sets the rowStatus
to notInService for those rows that cannot be included in the Neighbor
Report element for that interface."

STATUS current
DESCRIPTION
"This is a status variable. It is written by the SME when able to accept a new request.
Identifies a hint for the next value of dot11WNMRqstIndex to be used in a row creation attempt for dot11WNMRequestTable. If no new rows can be created for some reason, such as memory, processing requirements, etc, the SME shall set this attribute to 0. It shall update this attribute to a proper value other than 0 as soon as it is capable of receiving new measurement requests. The nextIndex is not necessarily sequential nor monotonically increasing."
::= { dot11WNMRequest 1 }

dot11WNMRequestTable OBJECT-TYPE
SYNTAX SEQUENCE OF Dot11WNMRequestEntry
MAX-ACCESS not-accessible
STATUS current
DESCRIPTION
"This group contains the current list of requests for WNM reports to be issued and have been issued until removed. A network manager adds a WNM request by creating a row with createAndWait row status and then filling in the request parameters/attributes. The request becomes active to be issued when the row status is set to Active. The columnar objects or attributes other than the rowStatus shall not be written if the rowStatus is Active. The request rows can be deleted, if commanded by a network manager via changing the value of dot11WNMRqstRowStatus to Destroy. This may leave orphaned rows if a manager crashes and forgets which rows are being used by it. One recommended way to manage orphaned or finished rows is to delete rows if their dot11WNMRqstRowStatus remains other than Active for longer than a period (recommend at least 5 minutes, IETF RFC 2579). Or another recommended way is to delete older rows as needed based on their dot11WNMRqstTimeStamp values. This can be done by the agent as well as the manager."

STATUS current
DESCRIPTION
"This is a status variable.
It is written by the SME when a management report is completed.

This attribute indicates the Manufacturer antenna type string for the
reported Manufacturer Information STA Diagnostic. The first octet of this
string indicates the antenna count, and the second octet indicates the
antenna gain. The antenna gain indicates the peak gain in dBi of the
antenna connected to the wireless network adaptor. The remaining octets
contain an ASCII string indicating the type of antenna connected to the
wireless network adaptor."

DESCRIPTION
"This is a control variable.
It is written by an external management entity.
Changes take effect as soon as practical in the implementation.

This attribute indicates the number of octets in a PSDU, below which an
RTS/CTS handshake is not performed, except as RTS/CTS is used as a cross
modulation protection mechanism as defined in 9.23. An RTS/CTS handshake
is performed at the beginning of any frame exchange sequence where the
PSDU is of type Data or Management, the PSDU has an individual address in
the Address1 field, and the length of the PSDU is greater than this
threshold. Setting this attribute to be larger than the maximum PSDU size
has the effect of turning off the RTS/CTS handshake for frames of Data or
Management type transmitted by this STA. Setting this attribute to 0 has
the effect of turning on the RTS/CTS handshake for all frames of Data or
Management type transmitted by this STA."

STATUS current
DESCRIPTION
"This is a control variable. It is written by an external management entity. Changes take effect as soon as practical in the implementation.

This attribute specifies the current maximum size, in octets, of the MPDU that may be delivered to the security encapsulation. This maximum size does not apply when an MSDU is transmitted using an HT-immediate or HT-delayed Block Ack agreement, or when an MSDU or MMMPDU is carried in an A-MPDU. Fields added to the frame by security encapsulation are not counted against the limit specified by this attribute. Except as described above, an MSDU or MMMPDU is fragmented when the resulting frame has an individual address in the Address1 field, and the length of the frame is larger than this threshold, excluding security encapsulation fields. The default value for this attribute is the lesser of 8000 or the aMPDUMaxLength or the aPSDUMaxLength of the attached PHY and the value never exceeds the lesser of 8000 or the aMPDUMaxLength or the aPSDUMaxLength of the attached PHY."

STATUS current
DESCRIPTION
"This is a control variable.
It is written by an external management entity or the SME.
Changes take effect as soon as practical in the implementation.

This attribute contains the national subdivisions (state, Region, prov-
ince, prefecture). Example: California. The A1 element is used for the top
level subdivision within a country. In the absence of a country-specific
guide on how to use the A-series of elements, the second part of the ISO
3166-2 code [ISO.3166-2] for a country subdivision SHOULD be used. The ISO
3166-2 code is a formed of a country code and hyphen plus a code of one,
two or three characters or numerals. For the A1 element, the leading coun-
try code and hyphen are omitted and only the subdivision code is included.

For example, the codes for Canada include CA-BC, CA-ON, CA-QC;Luxembourg
has just three single character codes: LU-D, LU-G And LU-L; Australia uses
both two and three character codes: AU-ACT, AU-NSW, AU-NT; France uses
numerical codes for mainland France and letters for territories: FR-75,
FR-NC."

Annex D
(normative)

Regulatory references

D.1 External regulatory references

This annex and Annex E provide information and specifications for operation in many regulatory domains.

WLANs implemented in accordance with this standard and the specifications and definitions referenced in it are subject to equipment certification and operating requirements established by regional and national regulatory administrations. The specification establishes minimum technical requirements for interoperability, based upon established regulations at the time this standard was issued. These regional and national regulations are subject to revision or may be superseded. Regulatory requirements that do not affect interoperability are not addressed in this standard. Implementers are referred to the regulatory sources in Table D-1 for further information. Operation in countries within defined regulatory domains may be subject to additional or alternative national regulations.

The documents listed in Table D-1 specify current regulatory requirements for various frequency bands and geographic areas at the time this standard was developed. They are provided for information only and are subject to change or revision at any time.

---

*Frequency planning for licensed STAs in Japan is performed by the regulatory authority and the licensees, addressing the coexistence among STAs operating with a variety of air propagation times and the coexistence between STAs using 20 MHz channel spacing, STAs operating with 10 MHz channel spacing, and STAs operating with 5 MHz channel spacing. Note also the CCA mechanism is preserved in licensed operation.
Behavior limits sets are listed in Table D-2.

</table>

**NOTE**—The fields that specify the 40 MHz channels are described in 20.3.15.4.

<sup>a</sup>For 20 MHz operation where the operating class signifies 40 MHz channel spacing, the 20 MHz channel corresponds to the channel number indicated.

<sup>b</sup>Procedures that may be used to improve sharing spectrum in addition to explicit regulatory requirements.
D.2 Radio performance specifications

D.2.1 Transmit and receive in-band and out-of-band spurious emissions

Spurious transmissions from compliant devices shall conform to national regulations.

D.2.2 Transmit power levels

The maximum allowable output power is measured in accordance with practices specified by the appropriate regulatory bodies.

The maximum allowable STA transmit power classifications for ITS nonmobile operations in the U.S. 5.85–5.925 GHz band are shown in Table D-3.

<table>

</tr>
</tbody>
</table>

D.2.3 Transmit spectrum mask

Transmit spectrum masks defined in regulation are subject to change or revision at any time.

For operation in the 5.85–5.925 GHz band the transmitted spectrum shall be as follows:

a) For any STA using 5 MHz channel spacing, the transmitted spectral density shall have a 0 dBr bandwidth not exceeding 4.5 MHz and shall not exceed the spectrum mask created using the permitted power spectral density levels listed in Table D-4 for the transmit power class of the STA.

b) For any STA using 10 MHz channel spacing, the transmitted spectral density shall have a 0 dBr bandwidth not exceeding 9 MHz and shall not exceed the spectrum mask created using the permitted power spectral density levels listed in Table D-5 for the transmit power class of the STA.

c) For any STA using 20 MHz channel spacing, the transmitted spectral density shall have a 0 dBr bandwidth not exceeding 18 MHz and shall not exceed the spectrum mask created using the permitted power spectral density levels listed in Table D-6 for the transmit power class of the STA.

</tr>
</tbody>
</table>
The transmit spectral mask is created and applied as shown in Figure D-1 about the channel center frequency (Fc) defined by the channel starting frequency and channel number from the operating class. The 0 dBr level is the maximum power spectral density measured in the channel. The measurements of transmit spectral density are made using a 100 kHz resolution bandwidth and a 30 kHz video bandwidth.

![Transmit Spectrum Mask and Application](image)

**Figure D-1—Transmit spectrum mask and application**

### D.2.4 Transmit Mask M

This subclause defines the characteristics of transmit mask M.

The power spectral density of the emissions shall be attenuated below the output power of the transmitter as follows:

- **a)** On any frequency removed from the center frequency between 0-45% of the channel bandwidth (BW): 0 dB.
- **b)** On any frequency removed from the center frequency between 45-50% of the channel bandwidth: $568 \log \frac{\% \text{ of BW}}{45}$ dB.
- **c)** On any frequency removed from the center frequency between 50-55% of the channel bandwidth: $26 + 145 \log \frac{\% \text{ of BW}}{50}$ dB.
- **d)** On any frequency removed from the center frequency between 55-100% of the channel bandwidth: $32 + 31 \log \frac{\% \text{ of BW}}{55}$ dB.
- **e)** On any frequency removed from the center frequency between 100-150% of the channel bandwidth: $40 + 57 \log \frac{\% \text{ of BW}}{100}$ dB.
- **f)** On any frequency removed from the center frequency between above 150% of the channel bandwidth: 50 dB or $55 + 10 \log (P)$ dB, whichever is the lesser attenuation.
- **g)** The 0 dB reference is measured relative to the highest average power of the fundamental emission measured across the designated channel bandwidth using a resolution bandwidth of 100 kHz and a video bandwidth of 30 kHz. The power spectral density is the power measured within the resolution bandwidth of the measurement device divided by the resolution bandwidth of the measurement device. Emission levels are also based on the use of measurement instrumentation employing a resolution bandwidth of at least one percent of the occupied bandwidth.
D.2.5 CCA-ED threshold

For OFDM PHY operation with CCA-ED, the thresholds shall be less than or equal to –72 dBm for 20 MHz channel widths, –75 dBm for 10 MHz channel widths, and –78 dBm for 5 MHz channel widths (minimum sensitivity for BPSK, R=1/2 + 10 dB in Table 18-14).
Annex E

(normative)

Country elements and operating classes

E.1 Country information and operating classes

WLANs implemented in accordance with this standard and the specifications and definitions referenced in it may be subject to equipment certification and operating requirements established by regional and national regulatory administrations. The specification establishes minimum technical requirements for interoperability, taking into consideration established regulations at the time this standard was issued. These regional and national regulations may be revised or may be superseded. Regulatory requirements that do not affect interoperability are not addressed in this standard. Implementers are referred to the regulatory sources in Table D-1 and their successors for further information. Operation in countries within defined regulatory domains may be subject to additional or alternative national regulations.

The Country element (see 8.4.2.10) allows a STA to configure its PHY and MAC for operation when the operating triplet of Operating Extension Identifier, Operating Class, and Coverage Class fields is present. The operating triplet indicates both PHY and MAC configuration characteristics and operational characteristics. The First Channel Number field of subsequent subband triplet(s) is based on the dot11ChannelStartingFactor that is indicated by the Operating Class field.

The operating class is an index into a set of values for radio operation in a regulatory domain. The operating class tables also contain pointers to behaviors and signal detection limits in Annex D where further operational requirements may be found.

The channel starting frequency variable is a frequency, used together with a channel number, to calculate a channel center frequency.

Channel spacing is the frequency difference between nonoverlapping adjacent channel center frequencies when using the maximum bandwidth allowed for this operating class.

The channel set is the list of integer channel numbers that are legal for a regulatory domain and class.

A behavior limits set is an enumerated list, each element of which points to a row in Table D-2 containing behavior limits in various regulatory domains.

Operating classes for operation in the United States are enumerated in Table E-1

</table>
Operating classes for operation anywhere in the world are enumerated in Table E-4, and are used in addition to the operating classes enumerated in Table E-1, Table E-2, and Table E-3 (see 8.4.2.56). Where a BSS includes STAs that do not support global operating classes, then all requests and Action frames to those STAs that convey elements containing operating classes shall use nonglobal operating class values.

**NOTE**—The channel spacing for operating classes 34–55 is for the supported bandwidth rather than the operating bandwidth. In these regulatory domains, the AP operates in a 20/40 MHz BSS, and the operating bandwidth of a non-AP STA is either 20 MHz or 40 MHz.

*The channels 34, 38, 42, and 46 cannot be used after 2012.

Nonglobal operating classes refer to the operating classes enumerated in the leftmost column of Table E-1, Table E-2, and Table E-3 (see 8.4.2.56).

NOTE—The following example Country element (see Figure 8-90) describes USA operation (‘55’, ‘53’) using both Table E-1 class 12 (nonglobal) and Table E-4 class 81 (global) for 2.4 GHz band, 11 channels at 100 mW limit (in hexadecimal): ‘07’, ‘0F’, ‘55’, ‘53’, ‘04’, ‘C9’, ‘0’, ‘01’, ‘0B’, ‘64’, ‘C9’, ‘51’, ‘0’, ‘01’, ‘0B’, ‘64’.

Vendor Specific operating classes are used to carry information not defined in this standard within a single defined format, so that reserved operating classes are not usurped for nonstandard purposes and so that interoperability is more easily achieved in the presence of nonstandard information.

E.2 Band-specific operating requirements

E.2.1 General

Subclause E.2 contains requirements specific to particular bands and regulatory domains.

E.2.2 3650–3700 MHz in the United States

The registration authority is the FCC’s Universal Licensing System (ULS).

Regulations specify the following:

— Certified mobile and portable STAs do not need to be registered, but they “must” operate under the control of an enabling STA (using DSE procedures).
— A registered STA “must” be a fixed STA.
— A registered STA “must” not operate as an enabling STA until the licensee has registered it as a “base station” in ULS.

Enabling STAs and fixed STAs are registered STAs. Dependent non-AP STAs and dependent APs are dependent STAs.

STAs shall use the following:

— CS/CCA
— TPC
— DFS
— CCA-ED (See D.2.5)

No STA shall use channel switch announcement.

No station may transmit for more than 4 ms without carrier sensing, whether transmitting fragments or frames, unless it is controlled by another STA.

STAs shall have the following elements set to true:

— dot11L CIDTSERequired
— dot11SpectrumManagementRequired
— dot11MultiDomainCapabilityActivated
— dot11ExtendedChannelSwitchActivated

STAs shall be capable of receiving all channels associated with operating classes 13–15.

STAs shall be capable of transmitting on all channels associated with operating class 15.

STAs shall set the value of dot11DSETransmitDivisor to 256 and the other dot11DSE timer values as shown in Table E-5.

### Table E-5—DSE timer limits

<td>60</td>
</tr>
</tbody>
</table>

### E.2.3 5.9 GHz band in the United States (5.850–5.925 GHz)

STAs operating under the behavior limits set 17 in Table D-2 are required to be registered with the FCC ULS. The registration includes the following:

— Classification by coverage size, which is defined by EIRP, and
— Identification of channels the STA is permitted to use.

STAs shall be classified for operation in this band by their maximum transmit power capability, as listed in Table D-3 in D.2.2. STAs shall be compliant with the spectral emission requirements for their class listed in D.2.3.

STAs shall have dot11OCBActivated set to true.

### E.2.4 5.9 GHz band in Europe (5.855–5.925 GHz)

STAs shall have dot11OCBActivated set to true.

Annex G
(normative)

Frame exchange sequences

G.1 General

The allowable frame exchange sequences are defined using an extension of the EBNF format as defined in ISO/IEC 14977:1996 [B46]. The elements of this syntax that are used here are as follows:

- \([a]\) = a is optional.
- \(\{a\}\) = a is repeated zero or more times.
- \(n\{a\}\) = a is repeated n or more times. For example, \(3\{a\}\) requires 3 or more "a". This notation is an extension to ISO/IEC 14977 and equivalent to \(n*a\{a\}\) as defined in that standard.
- \(a|b|c|...\) = selection between mutually exclusive alternatives, a, b, c ....
- ( ) = grouping, e.g., "a (b|c)" is equivalent to "a b | a c".
- (* a *) = “a” is a comment. Comments are placed before the text they relate to.
- < > = order of frames not relevant. For example, <a b> is either "a b" or "b a."
- A rule is terminated by a semicolon ";

The meaning of whitespace is changed from ISO/IEC 14977. Terminals do not contain whitespace, and the concatenate-symbol (comma in ISO/IEC 14977) is replaced by white space. Whitespace appearing between terminals indicates concatenation. Otherwise, whitespace is not significant and is used to highlight the nesting of grouped terms.

Two types of terminals are defined:

- **Frames.** A frame is shown in **bold** and identified by its type/subtype (e.g., **Beacon**, **Data**). Frames are shown with an initial capital letter.

- **Attributes.** Attributes are shown in *italic*. An attribute is introduced by the "*+" character. The attribute specifies a condition that applies to the frame that precedes it. Where there are multiple attributes applied, they are generally ordered in the same order of the fields in the frame to which they refer. The syntax a+(b|c) where b and c are attributes is equivalent to (a+b) | (a+c).

Nonterminals of this syntax are shown in a normal font, i.e., a sequence of words joined by hyphens (e.g., cf-frame-exchange-sequence).

The attributes are defined in Table G-1.

### Table G-1—Attributes applicable to frame exchange sequence definition

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>a-mpdu</td>
<td>Frame is part of an A-MPDU aggregate.</td>
</tr>
<tr>
<td>a-mpdu-end</td>
<td>Frame is the last frame in an A-MPDU aggregate.</td>
</tr>
<tr>
<td>block-ack</td>
<td>QoS data frame has ack policy equal to Block Ack.</td>
</tr>
<tr>
<td>broadcast</td>
<td>Frame RA is the broadcast address.</td>
</tr>
<tr>
<td>CF</td>
<td>Beacon contains a CFP element.</td>
</tr>
</tbody>
</table>
Table G-1—Attributes applicable to frame exchange sequence definition  *(continued)*

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>CF-Ack</strong></td>
<td>Data type CF-Ack subtype bit equal to 1 or CF-End+CF-Ack frame.</td>
</tr>
<tr>
<td><strong>CF-Poll</strong></td>
<td>Data type CF-Poll subtype bit equal to 1.</td>
</tr>
<tr>
<td><strong>csi</strong></td>
<td>An Action frame carrying channel state feedback (i.e., CSI, uncompressed beamforming, or compressed beamforming feedback matrices).</td>
</tr>
<tr>
<td><strong>csi-request</strong></td>
<td>A +HTC frame with the Feedback Request field equal to a value &gt; 0.</td>
</tr>
<tr>
<td><strong>delayed</strong></td>
<td>BlockAck or BlockAckReq under a delayed policy.</td>
</tr>
<tr>
<td><strong>delayed-no-ack</strong></td>
<td>BlockAck or BlockAckReq frame has No Ack policy.</td>
</tr>
<tr>
<td><strong>DTIM</strong></td>
<td>Beacon is a DTIM.</td>
</tr>
<tr>
<td><strong>frag</strong></td>
<td>Frame has its More Fragments field equal to 1.</td>
</tr>
<tr>
<td><strong>group</strong></td>
<td>Frame RA has i/g bit equal to 1.</td>
</tr>
<tr>
<td><strong>HTC</strong></td>
<td>+HTC frame, i.e., a frame that contains the HT Control field, including the Control Wrapper frame. See NOTE.</td>
</tr>
<tr>
<td><strong>implicit-bar</strong></td>
<td>QoS data frame in an A-MPDU with Normal Ack policy.</td>
</tr>
<tr>
<td><strong>individual</strong></td>
<td>Frame RA has i/g bit equal to 0.</td>
</tr>
<tr>
<td><strong>last</strong></td>
<td>Frame has its More Fragments field equal to 0.</td>
</tr>
<tr>
<td><strong>L-sig</strong></td>
<td>L-sig duration not equal to PPDU duration.</td>
</tr>
<tr>
<td><strong>action-no-ack</strong></td>
<td>Management frame of subtype Action No Ack.</td>
</tr>
<tr>
<td><strong>mfb</strong></td>
<td>A +HTC frame with the MFB field is not equal to all ones.</td>
</tr>
<tr>
<td><strong>more-psmp</strong></td>
<td>A PSMP frame with the More PSMP field equal to 1.</td>
</tr>
<tr>
<td><strong>mrq</strong></td>
<td>A +HTC frame with the MRQ subfield equal to 1.</td>
</tr>
<tr>
<td><strong>ndp-announce</strong></td>
<td>A +HTC frame with the NDP Announcement subfield equal to 1.</td>
</tr>
<tr>
<td><strong>no-ack</strong></td>
<td>QoS Data frame has ack policy equal to No Ack.</td>
</tr>
<tr>
<td><strong>no-more-psmp</strong></td>
<td>A PSMP frame with the More PSMP field equal to 0.</td>
</tr>
<tr>
<td><strong>normal-ack</strong></td>
<td>QoS Data frame has ack policy equal to Normal Ack.</td>
</tr>
<tr>
<td><strong>non-QAP</strong></td>
<td>Frame is transmitted by a non-AP QoS STA.</td>
</tr>
<tr>
<td><strong>non-stbc</strong></td>
<td>PPDU TXVECTOR STBC parameter is equal to 0.</td>
</tr>
<tr>
<td><strong>null</strong></td>
<td>Data type Null Data subtype bit equal to 1.</td>
</tr>
<tr>
<td><strong>pifs</strong></td>
<td>Frame is transmitted following a PIFS.</td>
</tr>
<tr>
<td><strong>psmp-ack</strong></td>
<td>Ack Policy field of QoS data frame is equal to PSMP Ack.</td>
</tr>
<tr>
<td><strong>QAP</strong></td>
<td>Frame is transmitted by a QoS AP.</td>
</tr>
<tr>
<td><strong>QoS</strong></td>
<td>Data type QoS subtype bit equal to 1.</td>
</tr>
<tr>
<td><strong>RD</strong></td>
<td>Frame includes an HT Control field in which the RDG/More PPDU subfield is equal to 1.</td>
</tr>
<tr>
<td><strong>self</strong></td>
<td>Frame RA = TA.</td>
</tr>
<tr>
<td><strong>sounding</strong></td>
<td>PPDU TXVECTOR SOUNDING parameter is present and equal to SOUNDING.</td>
</tr>
<tr>
<td><strong>stbc</strong></td>
<td>PPDU TXVECTOR STBC parameter is equal to a value &gt;0.</td>
</tr>
</tbody>
</table>
The allowable frame exchange sequence is defined by the rule frame sequence. Except where modified by the pifs attribute, frames are separated by a SIFS.

(* This rule defines all the allowable frame exchange sequences *)

\[
\text{frame-sequence} =
\begin{cases}
(\text{CTS} (\text{Management} + \text{broadcast} | \text{Data} + \text{group}) ) | \\
(\text{CTS} | \text{RTS} \text{ CTS} | \text{PS-Poll} \{\text{frag-frame ACK} \} \text{last-frame ACK}) | \\
(\text{PS-Poll ACK}) | \\
( [\text{Beacon} + \text{DTIM}] \{\text{cf-sequence} \} [\text{CF-End} [+\text{CF-Ack}]]) | \\
\text{hcf-sequence} | \\
\text{mcf-sequence};
\end{cases}
\]

(* A frag-frame is a nonfinal part of an individually addressed MSDU or MMPDU *)

\[
\text{frag-frame} = (\text{Data} | \text{Management}) + \text{individual} + \text{frag};
\]

(* This is the last (or only) part of a an individually addressed MSDU or MMPDU *)

\[
\text{last-frame} = (\text{Data} | \text{Management}) + \text{individual} + \text{last};
\]

(* A cf-sequence expresses all the sequences that may be generated within a contention-free period. The first frame in this sequence is sent by the AP. *)

\[
\text{cf-sequence} =
\begin{cases}
(\text{Broadcast} *) \\
\text{Beacon} | \text{Management} + \text{broadcast} | \text{Data} + \text{group} [+\text{QoS}] | \\
(\text{Data} + \text{individual} + \text{CF-Poll} [+\text{CF-Ack}] | \\
(\text{Data} + \text{individual} + \text{CF-Ack} \{ \text{Data} + \text{null} + \text{CF-Ack} \} | \\
\text{Data} + \text{null} + \text{CF-Ack}) ) | \\
(\text{Data} + \text{null} + \text{CF-Ack}) | \\
(\text{Data} + \text{null} + \text{CF-Poll} [+\text{CF-Ack}] | \\
(\text{Data} + \text{null} | \\
(\text{Data} + \text{individual} (\text{Data} + \text{null} + \text{CF-Ack} | \text{ACK}) ) ) | \\
(\text{Management} + \text{individual} + \text{ACK}) | 
\end{cases}
\]
G.3 EDCA and HCCA sequences

(* All the sequences initiated by an HC *)

hcf-sequence;

(* An hcf-sequence represents all the sequences that may be generated under HCCA. The sequence may be initiated by an HC within a CFP, or it may be initiated by a STA using EDCA channel access. *)

hcf-sequence =

( [CTS] 1{[Data +group [+QoS] ] | Management +broadcast} +pifs} | ([CTS] 1{txop-sequence} ) |

(* HC only, polled TXOP delivery *)

( [RTS CTS] non-cf-ack-piggybacked-qos-poll-sequence )

(* HC only, polled TXOP delivery *)

cf-ack-piggybacked-qos-poll-sequence |

(* HC only, self TXOP delivery or termination *)

Data +self +null +CF-Poll +QoS;

(* A cf-ack-piggybacked-qos-poll-sequence is the start of a polled TXOP that also delivers a CF-Ack. There are two main variants, polls that deliver data and, therefore, need acknowledgment and polls that do not. *)

cf-ack-piggybacked-qos-poll-sequence=

(qos-poll-requiring-no-ack +CF-Ack ( [CTS +self] polled-txop-content | polled-txop-termination) ) |

(qos-poll-requiring-ack +CF-Ack ( ACK ( polled-txop-content | polled-txop-termination) ) |

cf-ack-piggybacked-qos-data-sequence);

(* A non-cf-ack-piggybacked-qos-poll-sequence is the start of a polled TXOP that does not deliver a CF-Ack. Except for this, it is identical to the CF-Ack version. *)

non-cf-ack-piggybacked-qos-poll-sequence=

(qos-poll-requiring-no-ack ( [CTS +self] polled-txop-content | polled-txop-termination) ) |

(qos-poll-requiring-ack ( ACK ( polled-txop-content | polled-txop-termination) ) |

cf-ack-piggybacked-qos-data-sequence);

(* This sequence is the delivery of a single frame that is the TXOP poll frame that does not require acknowledgment either because the frame carries no data or because the frame carries data that do not...
require immediate acknowledgment. *)
qos-poll-requiring-no-ack =
   Data +null +CF-Poll +QoS |
   Data +individual +CF-Poll +QoS +(no-ack|block-ack);

(* A qos-poll-requiring-ack is the delivery of a single frame that is a TXOP poll frame, but also carries data that require immediate acknowledgment. *)
qos-poll-requiring-ack =
   Data +individual +CF-Poll [+CF-Ack] +QoS +normal-ack;

(* Polled-txop-content is what may occur after the delivery of a polled TXOP. A QoS STA transmits the first frame in this sequence *)
polled-txop-content =
   l {txop-sequence} [polled-txop-termination];

(* A polled-txop-termination may be used by a QoS STA to terminate the polled TXOP. The data frame is addressed to the HC, which regains control of the medium and may reuse any unused polled TXOP duration. *)
polled-txop-termination =
   Data +individual +null +QoS +normal-ack ACK;

(* A TXOP (either polled or EDCA) may be filled with txop-sequences, which are initiated by the TXOP holder. *)
txop-sequence =
   ( ((RTS CTS) | CTS +self) Data +individual +QoS +(block-ack | no-ack) ) |
   [RTS CTS] (txop-part-requiring-ack txop-part-providing-ack )|
   [RTS CTS] (Management | (Data +QAP)) +individual ACK |
   [RTS CTS] (BlockAckReq BlockAck) |
   ht-txop-sequence;

(* These frames require acknowledgment *)
txop-part-requiring-ack =
   Data +individual [+null] |
   Data +individual [+null] +QoS +normal-ack |
   BlockAckReq +delayed |
   BlockAck +delayed;

(* These frames provide acknowledgment to the txop-part-requiring-ack *)
txop-part-providing-ack=
   ACK |
   cf-ack-piggybacked-qos-poll-sequence | (* An HC responds with a new polled TXOP on expiry of current TXOP *)
   cf-ack-piggybacked-qos-data-sequence | (* An HC responds with CF-Ack and its own data on expiry of TXOP *)
   Data +CF-Ack;

(* An HC has received a frame requiring Ack with a duration value indicating the end of the TXOP. The HC continues the CAP by transmitting its own data. *)
cf-ack-piggybacked-qos-data-sequence =
\[\text{(Data} + \text{individual} + \text{CF-Ack} + \text{QoS} + \text{(no-ack|block-ack) polled-txop-content}) \mid \text{(Data} + \text{individual} + \text{CF-Ack} + \text{QoS} + \text{normal-ack} (\text{ACK polled-txop-content}) \mid \text{Data} + \text{CF-Ack} \mid \text{cf-ack-piggybacked-qos-poll-sequence})\] ;

(* An mcf-sequence represents all the sequences that may be generated under MCF. The sequence may be initiated by a mesh STA using EDCA channel access or MCCA channel access. *)

\[\text{mcf-sequence} = (\text{[CTS]} \mid \{(\text{Data} + \text{group} + \text{QoS}) \mid \text{Management} + \text{broadcast}\} \mid (\text{[CTS]} 1\{\text{txop-sequence}\}) ) \mid \text{group-mccaop-abandon};\]

(* A group-mccaop-abandon is the delivery of a single QoS Null frame by a mesh STA that has dot11MCCAActivated true. *)

\[\text{group-mccaop-abandon} = \text{Data} + \text{broadcast} + \text{null} + \text{QoS}\]

### G.4 HT sequences

(* The ht-txop-sequence describes the additional sequences that may be initiated by an HT STA that is the holder of a TXOP *)

\[\text{ht-txop-sequence} = \text{L-sig-protected-sequence} \mid \text{ht-nav-protected-sequence} \mid \text{dual-cts-protected-sequence} \mid 1\{\text{initiator-sequence}\};\]

(* an L-sig-protected-sequence is a sequence protected using the L-sig TXOP protection feature *)

\[\text{L-sig-protected-sequence} = \text{L-sig-protection-set} 1\{\text{initiator-sequence}\} \text{resync-sequence};\]

(* an ht-nav-protected sequence consists of setting the NAV, performing one or more initiator-sequences and then resetting the NAV if time permits *)

\[\text{ht-nav-protected-sequence} = \text{nav-set} 1\{\text{initiator-sequence}\} [\text{resync-sequence}];\]

(* a dual-cts-protected-sequence is a sequence protected using the dual CTS protection feature *)

\[\text{dual-cts-protected-sequence} = \text{dual-cts-nav-set} 1\{\text{initiator-sequence}\} [\text{dual-cts-nav-reset}];\]

(* a dual-cts-nav-set is an initial exchange that establishes NAV protection using dual CTS protection. *)

   BlockAck+HTC+ndp-announce NDP
  )
  ) |
(BlockAck+HTC+trq+delayed
  (ACK+sounding |
   ACK+HTC+ndp-announce NDP
  )
  ) |

(* The trq/sounding protocol also operates within aggregates. In this case the TRQ is carried in all +HTC frames (of which there has to be at least one) within the TRQ initiator’s transmission. The response PPDU either is a sounding PPDU, or carries at least one +HTC frame with an ndp-announce, in which case the following PPDU is an NDP sounding PPDU. The following syntax is an simplified representation of this sequence.*)

((BlockAck+HTC+trq+a-mpdu) {Data+HTC+trq+QoS+a-mpdu}+a-mpdu-end)

( ((BlockAck+HTC+a-mpdu]
    {Data+HTC+QoS+a-mpdu}+a-mpdu-end+sounding)
  ) |
( ([(BlockAck+HTC+ndp-announce+a-mpdu]
    {Data+HTC+ndp-announce+QoS+a-mpdu}+a-mpdu-end)
  ) NDP |
  (BlockAck+HTC+sounding) |
  (BlockAck+HTC+ndp-announce NDP);

(* During operation of explicit transmit beamforming (explicit-txbf), there are three encodings of feedback information. These are not distinguished here and are all identified by the csi attribute. The feedback position may be immediate, aggregate, or delayed. Immediate feedback follows a SIFS after the sounding PPDU (identified by the sounding attribute) or the NDP. Aggregate feedback occurs during an aggregate within the same TXOP and may accompany data frames in the same PPDU. Delayed feedback occurs during a subsequent TXOP during which the CSI responder is TXOP initiator. Only immediate feedback is described in the syntax below. The frame indicating any csi-request is carried in a sounding PPDU or
followed by an NDP. The CSI response is carried in an Action No Ack frame, which may be aggregated with the BlockAck or Ack response frame.

There are also two sets of sequences "staggered" and "NDP" that use either staggered sounding, or NDP sounding respectively.

\[ \text{explicit-txbf} = \text{explicit-txbf-staggered} | \text{explicit-txbf-NDP} \]

(* Staggered sounding. In this case, the sounding request is present in a frame that also generates an immediate response. The response is aggregated with the feedback in an A-MPDU. *)

\[ \text{explicit-txbf-staggered} = \]

\[

Figure H-1—Ethertype 89-0d frame body

LLC is defined in ISO/IEC 8802-2:1998.

SNAP is defined in IEEE Std 802-2001. The formatting of the SNAP header is according to IETF RFC 1042. The Ethertype is set to 89-0d.

The Payload Type field is set to one of the values in Table H-1.

Table H-1—Payload Type field values

<table>
<thead>
<tr>

Annex J

(informative)

Formal description of a subset of MAC operation

J.1 Status of this annex

This annex is obsolete. Consequently this annex may be removed in a future revision of this standard. This clause is no longer maintained and may not be compatible with or describe all features of this standard.

J.2 Overview

This annex contains formal descriptions of the behavior of a subset of MAC STA and AP entities. These descriptions also describe the frame formats and the generation and interpretation of information encoded in MAC frames, in the parameters of service primitives supported by the MAC, and in MIB attributes used or generated by the MAC. The MAC is described using the 1992 version of the ITU Specification and Description Language (SDL-92). SDL-92 is defined in ITU-T Recommendation Z.100 (03/93). An update to ITU-T Recommendation Z.100 was approved in 1996 (SDL-96), but none of the SDL facilities used in this annex were modified. An introduction to the MAC formal description is provided in J.3. Definitions of the data types and operators used by the MAC state machines are provided in J.4. An SDL system describing MAC operation at an IEEE 802.11 STA is contained in J.5. Finally, a subset of an SDL system describing the aspects of MAC operation at an IEEE 802.11 AP that differ from operation at a non-AP STA is provided in J.6.

NOTE 1—The SDL definitions in this annex are expected to be usable with any SDL tool that supports the 1993 version or 1996 update of ITU-T Recommendation Z.100. Software for generating, analyzing, verifying, and simulating SDL system descriptions is available from several sources.

NOTE 2—The SDL code in this annex was generated using SDT/PC version 3.02; from Telelogic AB, Malmo, Sweden (+46-40-174700; internet: telelogic.se); U.S. office in Princeton, NJ (+1-609-520-1935; internet: telelogic.com). Telelogic offers SDT for several workstation platforms in addition to SDT/PC.

NOTE 3—The use of Telelogic’s product to prepare this annex does not constitute an endorsement of SDT by the IEEE LAN MAN Standards Committee or by the IEEE.

NOTE 4—The diagrams on the next two pages show most of the symbols of SDL graphical syntax (SDL-GR) used in the MAC formal description. The symbols in these diagrams have labels and comments that explain their meanings. These diagrams are intended to serve as a legend for the SDL-GR symbols that comprise most of the process interaction and state transition diagrams. These diagrams are neither a complete SDL system, nor a complete presentation of SDL-GR symbology. Also, this state machine fragment exists to illustrate the SDL graphical syntax and does not describe any useful behavior.
/* This is a text symbol, used to hold data type (sort) definitions, declarations, signal lists, and other SDL statements that have no graphical representation. */

Process State Machine Legend

- Process Start symbol (One per process, contains no text.)
- State symbol, arrowhead indicates transition(s) entering the state.
- Signal symbol with wedge on left side used for signals from LLC, SME, self, and others logically above or parallel to this process.
- Task symbol for algorithmic process steps
- 'start timer' set(end_time, timer)
- 'stop timer' reset(timer)
- Call procedure (parms)
- Call macro (parms)
- A signal at head of the process input queue that is not named in any of the state's input symbols is discarded unless named in a Save symbol attached to the state. * Save refers to all remaining signal names.
- Process Stop symbol
- Decision criterion

* in a state symbol means all states except those listed
- in a state symbol refers to the state from which the transition began

* (state x, state_y)

error_signal

'signal_z'

* in a state symbol 'when in any state' 'actions in response to signal_z'

'signal_z'

* in a state symbol 'when in state' 'actions to recover from error'

- state_N

'process (parms)'

result_1

result_2

output symbol with point to right side used for signals to PHY & others logically below this process

A Priority Input symbol enables its transition if the named signal is anywhere in the process input queue.
J.3 Introduction to the MAC formal description

This formal description defines the behavior of IEEE 802.11 MAC entities. The MAC protocol functional decomposition used herein facilitates explicit description of the reference points and durations of the various timed intervals; the bases for generation and/or validation of header fields, service parameters, and MIB attributes; and the interpretation of each value in cases where enumerated data types are used in service parameters.

J.3.1 Fundamental assumptions

The MAC protocol is described as an SDL system, which is a set of extended finite state machines. Each state machine is a set of independent processes, all of which operate concurrently. All variable data-holding entities and procedures exist solely within the context of a single process. In SDL all interprocess communication is done with signals (there are no global variables). Signals may be sent and received explicitly, using SDL’s output and input symbols, or implicitly, using SDL’s export/import mechanism (only if the variables or procedures are declared “remote”). By default, signals incur delays when traversing channels between blocks; however, only nondelaying channels and signal routes are used in the MAC state machines, and all remote variables and procedures are declared with the “nodelay” property.

State transitions, procedure calls, and tasks (assignment statements and other algorithmic processing steps) are assumed to require zero time. This permits the time intervals that are part of the normative MAC behavior to be defined explicitly, using SDL timers. One unit of system time (a 1.0 change in the value of “now”) is assumed to represent 1 μs of real time. Usec (microsecond) and TU data types are defined, with operators to convert Usec and TU values to SDL time or duration when necessary.

The SDL system boundary encloses the MAC entities. The LLC, SME, PHY, and DS are part of the environment. SDL generally assumes that entities in the environment operate as specified; however, the MAC state machines that communicate with the various SAPs attempt to validate inputs from the environment, and to handle cases where a pair of communicating entities, one within the system and the other outside the system boundary, have different local views of the medium, STA, or service state. All STAs in an IEEE 802.11 service set are assumed to exhibit the behaviors described herein. Nevertheless, because of the open nature of the WM, the MAC state machines check for error cases that can arise only when an entity on the WM is transmitting IEEE 802.11 protocol data units (PDUs), but is not obeying the communication protocols specified by this standard.

J.3.2 Notation conventions

When practical, names used in the clauses of this standard are spelled identically in this annex. The principal exceptions are those names that conflict with one of SDL’s reserved words (such as power management mode “active,” which is renamed “sta_active” in SDL). To help fit the SDL text into the graphic symbols, acronyms with multiple, sequential capital letters are written with only the first letter capitalized (e.g., “MSDU” is written “Msdu” and “MLMEJoin.request” is written “MlmeJoin.request”).

SDL reserved words and the names of variables and synonyms (named constants) begin with lowercase letters. The names of sorts (data types), signals, signal routes, channels, blocks, and processes begin with uppercase letters. The names of certain groups of variables and/or synonyms begin with a particular lowercase letter, followed by the remainder of the name, beginning with an uppercase letter. These groups are

“aNameOfAttribute”PHY operational parameters.
“cNameOfCapability”Capability bits, also used for internal values exported as MIB counters.
“dNameOfDuration”Duration (relative time) values, declared as Usec, TU, or Duration.
“dot11NameOfAttribute”MIB attributes.
“eNameOfElement”Element ID values.
“mNameOfVariable”Remote variables used for intra-MAC communication, but not part of the MIB.
Most of these variables are exported from the MLME block.
“sNameOfStaticValue”Synonyms for static data values used within the MAC.
“tNameOfTime”Time (absolute time) values, declared as Usec, TU, or Time. The names of timers begin with “T.”

J.3.3 Modeling techniques

State machines are grouped according to defined function sets that are visible, directly or indirectly, at an exposed interface. The emphasis in the organization of the state machines is explicitly to show initiation of and response to events at the exposed interfaces, and time-related actions, including those dependent on the absence of external events (e.g., response timeouts) and intervals measured in derived units (e.g., backoff “time” in units of slots during which the WM is idle). The operations associated with the various state transitions emphasize communication functions. Most of the details regarding insertion, extraction, and encoding of information in fields of the PDUs is encapsulated with the definitions of those fields. This approach, which relies heavily on SDL’s abstract data type and inheritance mechanisms, permits the behavior of the data-holding entities to be precisely defined, without obscuring process flow by adding in-line complexity to the individual state transitions.

The modeling of PDUs and service data units (SDUs) requires sorts such as octet strings, and operators such as bitwise boolean functions, which are not predefined in SDL. These sorts and operators are defined in Package macsorts, which appears in J.4.

PDU and SDU sorts are based on the Bit sort. Bit is a subtype of SDL’s predefined Boolean sort. As a result, Bit literals 0 and 1 are alternative names for “false” and “true” and have no numeric significance. To use 0 or 1 as integer values requires a conversion operation. Items of the Bitstring sort are 0-origin, variable-length strings of Bits. With Bitstring operands, operators “and,” “or,” “xor,” and “not” operate bitwise, with the length of the result equal to the length of the longest (or only) source string. The Octet sort is a subtype of Bitstring that adds conversion operators to and from Integer. Each item of the Octet sort has length=8 {by usage convention in Z.100, enforced in Z.105}. Items of the Octetstring sort are 0-origin, variable-length strings of Octets. The Frame sort is a subtype of Octetstring that adds operators to extract and to modify all MAC header fields and most other MAC frame fields and elements. Most MAC fields and elements that contain named values with specific value assignments or enumerations are defined as subtypes of Frame, Octetstring, or Bitstring with the names added as literals or synonyms, so that the state machines can refer to the names without introducing ambiguity about the value encodings.

Where communication at a SAP or between processes is strictly first in first out (FIFO), the (implicit) input queue of the SDL processes is used. When more sophisticated queue management is needed, a queue whose entries are instances of one, specified sort is created using the Queue generator. Entries on Queue sorts may be added and removed at either the tail or the head, and the number of queue entries may be determined. The contents of a Queue may also be searched to locate entries with particular parameter values.

In J.4 is an SDL-92 Package (a named collection of SDL definitions that can be included by reference into an SDL System specification), which is a formal description of the formats and data encodings used in IEEE 802.11 SDUs, PDUs, and the parameters of the service primitives used at each of the SAPs supported by the IEEE 802.11 MAC. This package also contains definitions for some data structures and operators used internally by one or more of the MAC state machines.

The behaviors of many intra-MAC operators are part of the normative description of the MAC protocol because results of the specified operations are visible, directly or indirectly, at exposed interfaces. For example, custom operators are used to define the generation of the CRC-32 value used in the FCS field (operator crc32, page 424), the calculation of frame transmission time used as part of the value in the
Duration/ID field in certain types of frames (operator calcDur, page 440), the comparison of the values of particular fields of a received MAC header with cached data values as part of the procedure for detecting duplicate frames (operator searchTupleCache, page 412), and numerous other aspects of frame formats and information encoding. On the other hand, data structures used solely for intra-MAC storage or for transferring of information between different state machines of a single STA or AP, are only normative to the extent that they define items of internal state and the temporal sequence necessary for proper operation of the MAC protocol. The specific structures and encodings used for internal data storage and communication functions in this formal description do not constrain MAC implementations, provided those implementations exhibit the specified behaviors at the defined SAPs and, in conjunction with an appropriate PHY, on the WM.

**J.4 Data type and operator definitions for the MAC state machines**

This clause is in SDL/PR (phrase notation), with the exception of procedural operators, which are defined in SDL/GR (graphic notation). Package macsorts contains the definitions of the sorts (data types with associated operators and literals) and synonyms (named constants) used by the MAC state machines. Package macmib defines data types for attributes in the MAC MIB, and portions of the PHY MIB, accessed by the MAC state machines. Package macmib exists solely to satisfy SDL’s strong type checking in the absence of an SDL tool that fully supports Z.105 (the combined use of SDL with ASN.1).

Discrete microsecond and Time Unit sorts

SDL does not define the relationship between its concept of Time and physical time in the system being described.

An abstraction is needed to establish this relationship, because Time in SDL uses the semantics of Real, whereas time in the MAC protocol is discrete, with the semantics of Natural and a step size (resolution) of 1 microsecond.

Most MAC times are defined using the subtypes of Integer, Usec and TU. These have operators for explicit conversion to SDL Time (tUsec, tTU), SDL Duration (dUsec, dTU), and from SDL Time (uTime, tuTime) as needed to comply with SDL's strong type checking.

Most MAC times are defined using the subtypes of Integer, Usec and TU. These have operators for explicit conversion to SDL Time (tUsec, tTU), SDL Duration (dUsec, dTU), and from SDL Time (uTime, tuTime) as needed to comply with SDL's strong type checking.

Microsecond sort -- also has operators tmin and tmax

newtype Usec inherits Integer

else

k := index to use for new cache entry

temp!full := true, temp!ta := taddr, temp!sn := tseq

temp!fn := tfrag, temp!tRx := tnow

cache(k) := temp

If a match is found with \{TA, SeqNum\}, update FragNum and tRx for that entry rather than creating a new (redundant) entry.

Select cacheIndex for new entry if no \{TA, SeqNum\} match. If possible, use an empty location, otherwise choose an entry to replace an entry selected based on unspecified criteria.

This procedural operator is part of sort TupleCache.
cache := updateTupleCache (addr, seq, frag, time)
First searches cache for an entry, matching the base frame, so that (ta = addr) and (sn = seq).
If such an entry exists, that entry is updated in place with (fn = frag) and (tRx = time).
If no such entry is found, a free entry, or a nonfree entry selected using an unspecified algorithm, is used for this frame, storing (ta = addr) and (sn = seq) and (fn = frag) and (tRx = time).

Frame sort (the basic definition of fields in MAC frames)

Frame is a subtype of Octetstring with operators for creating
MAC headers, extracting each of the header fields and some
management frame fields, and modifying most of these fields.
In addition, there are operators to create and extract management frame
elements, but no operators for the frame body, IV, ICV, and FCS
fields, which are handled directly as Octetstrings.

newtype Frame   inherits Octetstring   operators all;

adding  operators

TIM is a subtype of Octetstring with operators:

operator bufFrame : TIM, AsocId -> Boolean;
operator bufBcst  : TIM -> Boolean;
operator dtCount  : TIM -> Integer;
operator dtPeriod : TIM -> Integer;
axioms
for all el in TIM( for all a in AsocId(  
  bufFrame(el, a) ==
    if a < (octetVal(el(2) and 0xFE) * 8) then false
    else
      if a >= ((octetVal(el(2) and 0xFE)*8) + ((Length(el)-3)*8)) then false
      else
        Extract!(B_S(el), (a-(octetVal(el(2) and 0xFE)*8)+24)) = 1
      fi
    fi;
  bufBcst(el) == el(2) and 0x01 = 0x01;
  dtCount(el) == octetVal(el(0));
  dtPeriod(el) == octetVal(el(1))); );
endnewtype TIM;
Operator mkTim

```
; fpar
  trf TrafficMap,
  dtc Integer,
  xlo AsocId,
  xhi AsocId,
  bc Boolean
returns Octetstring;

  i; fpar
  trf TrafficMap,
  dtc Integer,
  dtp Integer,
  xlo AsocId,
  xhi AsocId,
  bc Boolean
returns Octetstring;

  Operator mkTim

  tim:= mkOS(dtc,1) //
               mkOS(dtp,1)

  i:= xlo,
  k:= xhi

  Search up from
  low limit (xlo)
  for a nonzero
  traffic map bit.

  Search down from
  high limit (xhi)
  for a nonzero
  traffic map bit.

  Floor starting
  index to even
  multiple of 8.

  Append octets
  in active part
  of bitmap to
  the TIM.

  Start TIM
  with DTIM
  count and
  period fields.

  If no 1s in the partial
  bitmap, generate TIM
  with index 0 and one
  octet =0 (see 7.3.2.6).

  This method of calculating bitmap
  index and octet count meets alignment
  and length restrictions implicit in
  the encoding of the TIM bitmap control
  field (7.3.2.6). However, if xlo is not a
  multiple of 16, or xhi is not a multiple
  of 8, bits outside the range (xlo:xhi)
  will appear in the TIM element. This
  may be of concern to implementers, but
  is not a problem in the formal description
  because criteria for selecting bitmap
  subsets are not part of this standard.

  /* This procedural operator is part
     of sort TrafficMap. mkTim builds
     the info field for a TIM element
     from the DTIM count and DTIM
     period values and the contents
     of the (xlo:xhi) range of bits in
     the TrafficMap. The resulting
     Octetstring can be used as an
     operand of mkElem (by an AP
     generating a Beacon frame). */
```

```
mkTim_1a(1)
```

```
This procedural operator is part of sort TrafficMap. nextAId searches upward from the specified initial index (x) in a TrafficMap and returns the index of the first bit = 1. If the end of the TrafficMap (index = sMaxAId) is reached with no 1s found, a value of 0 is returned. *
newtype Rate   inherits Octet   operators all;
adding  operators

------------------------------------------------------------------------
J.5 State machines for MAC STAs

The following SDL-92 system specification defines operation of the MAC protocol at an IEEE 802.11 STA. Many aspects of STA operation also apply to AP operation. These are defined in blocks and processes referenced from both the STA and AP system specifications. Blocks and processes used in both STA and AP are identifiable by the SDL comment /* for STA & AP */ below the block or process name. Blocks and processes specific to STA operation are identifiable by the SDL comment /* station version */ below the block or process name. The definitions of all blocks and processes referenced in the STA system specification appear in J.5.

The remainder of J.5 is the formal description, in SDL/GR, of an IEEE 802.11 STA.

This subclause describes the security behavior of only 11.2.2 and 11.2.3.

This subclause does not describe the behavior of a STA with QoS facility.

This clause does not describe the behavior of an HT STA.
System Station

Includes request validation and add/remove MAC headers.

MAC_Data_Service /* for STA & AP */

Includes encryption, fragmentation, and power save queuing.

MPDU_Generation_STA /* station version */

Includes DCF, Rts/Cts, Ack & CF-Ack, retries, CF-poll response, A tm handling, and PS-Poll.

Protocol_Control_STA /*station version*/

Includes scan, join, beacon/dwell and awake/doze timing, (re/dis)associate, (de)authenticate, start IBSS, and monitor of station & power save state.

Transmission /*for STA & AP*/

Includes valid ate, decrypt, address & duplicate filter, defragment, channel state (physical and virtual carrier sense), and IFS & slot timing.

Reception /*for STA & AP*/

Includes backoff, FCS generate, and timestamp insert.

This block provides the MAC_SAP functions, described in Clause 6, conveying MSDUs from and to the LLC entity. This block operates identically in STA and AP, but in STA the TSDU signal route connects directly to MPDU_Generation, and the RSDU signal route connects directly from Protocol_Control, whereas in AP both of these signal routes connect to Distribution Service. */
Process MSDU_to LLC

/* This process runs when reception is successfully completed on an MSDU addressed to the local LLC entity. This process extracts the appropriate address and status info, removes the MAC header from the MSDU data field (the FCS and IV/ICV are removed much earlier in reception handling), and generates the indication to LLC. Reception status is always "successful" because a receive error causes the MSDU to be discarded before reaching MAC Data Service. */

To LLC

MsduIndicate (sdu, cf)

da := addr1(sdu)

sa := if frDs(sdu)=1
    then addr3(sdu)
    else addr2(sdu) fi

srv :=
    if orderBit(sdu)=1
    then strictlyOrdered
    else reorderable fi

"* This process runs when
an MSDU to transmit is
presented by LLC. This
process validates request
parameters, and if valid
attaches a basic MAC
header and sends the MSDU
to MPDU preparation (at
STA) or to Distribution
Service (at AP). If request
is invalid, or when status
is available for the valid
Tx attempt, LLC is informed
by an MlinitdataStatus_
Indication generated by
this process. */
signal FragConfirm(FragSdu,TxResult), FragRequest(FragSdu);

Includes encryption if dot11PrivacyOptionImplemented = true. This is a typical location, but implementers may use other locations between the MAC_SAP and PHY_SAP_TX as long as they provide the specified behavior as observed at LLC, MLME and the WM.

* This block converts outgoing Msdu and Mmpdu into Mpdus, fragmenting and encrypting as necessary. If the station is in a Bss, outgoing Msdu are directed via distribution service at the AP.

The PM_Filter process queues frames needing announcement by Atim in an Ibss; or frames to be sent in the CF-period at a CF-pollable station in a Bss. *
Process Prepare_MPDU

```
imported m Assoc, mBss, dot11PrivacyInvoked Boolean;
imported dot11FragmentationThreshold Integer;
imported dot11WepDefaultKeys KeyVector;
imported dot11WepDefaultKeyId KeyIndex;
imported dot11WepKeyMappings KeyMapArray;
imported dot11WepKeyMappingLength KeyMapArrayLength;
imported mCap Octetstring;

/* This process generates one or more MPDUs from each outgoing Msdu or Mmpdu. If encryption is needed, the MPDUs are encrypted before being passed to be filtered for possible power save or CF queuing before tx. */
```

The diagram illustrates the flow of data and the process of generating MPDUs, including the preparation steps and the conditions under which encryption is applied. The code snippet highlights the parameters and variables used in the process, along with the conditions for encryption and fragmentation.

Process PM_Filter_STA

1. **Pre_Atim**
   - Wait until TxCoord sends AtimW signal to avoid chance that Beacon fsdu reaches TxCoord before the TBTT signal is processed by TxCoord.

2. **AtimW**
   - n := length(anQ)
   - n := n - 1
   - Move all anQ entries to psQ.

3. **PM_Ibss_AtimW**
   - *Ibss during Atim window.
   - (not atPend) and (not import (mAtimW))

4. **Frag_Request(fsdu)**
   - sentBcn := false
   - PM_Ibss_Data
   -碎片 Request (fsdu)
   - Pdu_Request (fsdu)
   - Pdu_Confirm (fsdu, resl)
   - Pdu_Request (fsdu)

5. **PsChange**
   - sentBcn := false
   - Pdu_Confirm (fsdu, resl)
   - Pdu_Request (fsdu)
   - PsChange (fsdu, resl)

6. **PsResponse (psm)**
   - Move fsdus that arrive before beacon back onto end of input queue.
   - Handling is implementation dependent, can either re-queue until next atim window or retry during this atim window.

7. **PsInquiry (fsdu!dst)**
   - Pdu_Request (fsdu)

8. **Wait_PS_Response**
   - Frag_Request(fsdu) to Self

9. **PsResponse (psm)**
   - Move all anQ entries to psQ.

10. **PsInquiry (fsdu!dst)**
    - Ensure that beacon is first fsdu sent during Atim window.
    - PsResponse (psm)
This block performs the DCF functions, as well as CF-responder functions if the station is CF-pollable. Tx_Coordination includes RTS and ATIM generation. Rx_Coordination generates acknowledgments, routes data frames to MAC data service and management frames to MLME, and indicates receipt of Ack, Cts, and CF-Poll frames to Tx_Coordination. 

Includes the CF responder if station is CF-pollable.

/* RANDOM NUMBER FUNCTION */
imported procedure Random;
fpar limit Integer; returns Integer;

Imported dot11RtsThreshold, dot11ShortRetryLimit, dot11LongRetryLimit, dot11FragmentationThreshold, dot11MaxTransmitMsduLifetime Integer, mPdly Usec;
These transitions are only present at CF-pollable stations.

Entry when station wakes up to transmit.

Test if fsdu seq number and tx lifetime set.

See 9.6 for rules about selecting transmit data rate.

With FH PHY, if next fragment will be after a dwell boundary, Duration/ID may be set to one ACK time plus SIFS time.
See 9.2.11

CTS to self is a protection mechanism. (see 9.10)

Use CTS to self?

(yes)

RTS/CTS is a protection mechanism. (see 9.10)

Send RTS/CTS

BkDone(stat)

BkDone(stat)

Backoff(ccw,-1)

Transmit length(tpdu),txrate, frametime2)

rtsdu:= mkctl(rts, frametime2 + (3*aSifstime) + (2*ackctstime))

Send rts

End rts

Send rts
This shows the case where the same pdu is retried after the backoff. It is also allowable to return this pdu to PM_Filter with status=partial, and to go to TxC_Backoff state with cont=false. This will allow a different pdu (if available) to be sent as the next transmission.
**PM_F Filter ensures that a beacon frame will be the first first sent after Tbt.**

* This block does octet-level transfers of MPDUs from the MAC to the PHY transmitter, generating FCS fields and inserting timestamp values where necessary. Process Data_Pump begins transmitting when TxRequest arrives. The sender of TxRequest is assumed to have done the appropriate actions prior to transmitting onto the WM. If these actions include performing random backoff or invoking the "backoff procedure" (see 9.2.5.2), a Backoff signal is sent to process Backoff. At the completion of each backoff, a BkDone signal is returned to the sender of the Backoff signal at the correct time to send a TxRequest. The medium state updates (busy, idle, slot) from Channel_State are forwarded to Backoff_Procedure via Data_Pump to prevent decrementing the backoff count while transmitting Cts or Ack frames. This block is used in both station and AP. *
* This process sends an Mpdu to the Phy while generating & appending the Fcs. On beacons and probe responses inserts (TSF + Phy TxDelay) in the timestamp field at confirm of octet 23.

To transmit after Sifs, send TxRequest at end of the M1 interval (see 9.2.10). For Pifs, Difs, or any backoff slot, TxRequest is sent at the end of the appropriate M2 interval. */
Process Backoff_Procedure

/* This process performs the Backoff Procedure (see 9.2.5.2), returning Done(-1) when Tx may begin, or Done(n>=0) if cancelled. Backoff(cw,-1) starts new random backoff. Backoff(x,n>=0) resumes cancelled backoff. Backoff(0,0) sends Done(-1) when WM idle. */

* Input Signal Summary
BUSY is sent by Channel_State when the WM changes from idle to busy due to CCA and/or NAV, and by Data_Pump at TxStart. CANCEL is sent by TxCoordination to terminate a backoff and return the residual backoff count value. IDLE is sent by Channel_State at the end of the M2 interval (see 9.2.10) that busy WM has been idle (CCA & NAV) for DIFS (EIFS after Rx error). SLOT is sent by Channel_State at the end of each M2 interval (see 9.2.10) while the WM is idle. Busy, Idle and Slot are forwarded from Channel_State via Data_Pump when transmit is not in progress. */

* RANDOM NUMBER FUNCTION *
imported procedure Random;
fpars limit Integer; returns Integer;
* This function returns an integer from a uniform distribution over the range (0 <= value <= limit). Implementers need to be aware that proper operation of the MAC protocol requires statistically independent pseudo-random sequences to be generated by each station in a service area. */
Process Backoff_Procedure

Idle
- Idle signal not sent if WM free. This consumes any Idles still on input queue.

Slot
- slotCnt:= slotCnt - 1

Busy
- Go back and wait for WM to become idle.

Channel_Idle
- Finish at M2 of proper slot, even if slotCnt = 0 at entry to state.

channel_Busy
- slotCnt = 0

Cancel
- Cancel has priority over other transitions. Done() returned if Cancel arrives at instant slotCnt = 0.

BkDone(slotCnt) to source
- BkDone(slotCnt) to source

Done
- Done sent with value -1 when backoff counts down to zero.

Done(0) returned if Cancel arrives at instant slotCnt = 0.

snd_BkDn
/* In this block are the MAC MIB and MLME_SAP service primitives described in Clause 10. The MLME services are performed in the MLME block. This block is used both in station and AP. */
This state machine passes indications through, unmodified, from MLME to the MLME SAP. MlmeAssociate.indication and MlmeReassociate.indication are only generated by MLME at APs.
Process MIB

Mib_access_1a(2)

/* This process performs MlmeGet, MlmeSet, and MlmeReset functions. MIB access and update is described informally to avoid creating a full definition of the MIB in SDL (and anticipating the integration of the ASN.1 MIB definition using Z.105). */

ResetMAC is sent to all processes in all blocks. However, to reduce clutter and enhance readability, ResetMAC is omitted from signalists and signal routes needed solely for the ResetMAC signal are not shown.

Reset read-write attributes in the MAC MIB. The write-only attributes in the privacy group may also be reset. If there is a (non-Mlme) means to alter any of the read-only attribute values, they must be restored to default values.

A locally-administered MAC address may be used in lieu of the unique, globally-administered MAC address assigned to the station. However, the value of dot11MacAddress may not change during MAC operation.

When there is no association info, station state is identical to authentication state.
Each of these ovals represents a SERVICE. Each service contains the state transitions to handle a DISJOINT SUBSET of the input signal set of this process. Services share local variables and the input queue. At any instant, a state transition can occur in, at most, one service – the service which handles the kind of signal at the head of the process input queue.

/* This service routes mmpdu and station state update signals from and to the mlme operational services. Signals are not modified, but some superfluous parameters are omitted in transfer. */

The selection criteria for Mmpdu Tx data rate are not specified. Frames to group addresses must use one of the basic rates. Requests should use one of the basic rates unless the operational rates of the recipient station are known. Responses must use a basicrate or the rate at which the request was received.

Mmpdu only needed for probe responses and beacons.
This service handles (De)Authenticate requests. This service also handles incoming the generation of responses for class 2 errors.

This state machine handles Mlme requests sequentially, which is the simplest case. It is permissible to have several authentications in progress at once, provided the destination stations are all different. To support concurrent sequences this state machine gets collapsed into one state, with sequence state held in a variable. The local variables are replicated for each sequence, selected by responder address. *
Deauthenticate request and class 2 error are on this page.

/* This process filters valid received frames by destination address, and 
Bssid for group destination addresses. This process also maintains received 
pdu counters and the tuple cache for detecting duplicated unicast frames. 

Data and management frames which need acknowledgment cause a 
NeedAck signal to Protocol_Control as well as an RxMpdu to Defragment. 
Piggybacked CfAcks cause RxCfack signals, and CfPolls cause RxCfpoll 
signals to Protocol_Control. If an RxCfpoll is sent for a Data+CfPoll 
or Data+CfPoll+CfAck, the NeedAck has to reach TxCoord during the Sifs. 
(The data frame report cannot serve this purpose because the payload may 
be a nonfinal fragment.)

Duration and CfP duration remaining are reported to Channel_State, and 
power save mode is reported to Mlme. */

J.6 State machines for MAC AP

The following SDL-92 system specification defines operation of the MAC protocol at an IEEE 802.11 AP. Many aspects of AP operation are identical to the STA operation. These are defined in blocks and processes referenced from both the STA and AP system specifications. Blocks and processes used in both STA and AP are identifiable by the SDL comment /* for STA & AP */ below the block or process name. Blocks and processes specific to AP operation are identifiable by the SDL comment /* AP version */ below the block or process name. Definitions for the /* AP version */ and the /* STA & AP */ blocks and processes appear in this subclause.

The remainder of this subclause is the formal description, in SDL/GR, of an IEEE 802.11 AP.

This subclause describes the security behavior of only 11.2.2 and 11.2.3.

This subclause does not describe the behavior of a STA with QoS facility.

This block provides the MAC_SAP functions, described in Clause 6, conveying MSDUs from and to the LLC entity. This block operates identically in STA and AP, but in STA the TSDU signal route connects directly to MPDU_Generation, and the RSDU signal route connects directly from Protocol_Control, whereas in AP both of these signal routes connect to Distribution Service. */
Process MSDU_to_LLCE

/* This process runs when reception is successfully completed on an MSDU addressed to the local LLC entity. This process extracts the appropriate address and status info, removes the MAC header from the MSDU data field (the FCS and IV/ICV are removed much earlier in reception handling), and generates the indication to LLC. Reception status is always "successful" because a receive error causes the MSDU to be discarded before reaching MAC Data Service. */

DS_Idle

State continued from previous page.
This block converts outgoing Msdus and Mmpdus into Mpdus, fragmenting and encrypting as necessary. The PM_Filter_AP process queues frames needing announcement in a TIM, and frames to be sent during the CF period at an AP with an active point coordinator. This process also adds the TIM element to outgoing Beacon frames. */

Includes encryption if dot11PrivacyOptionImplemented = true. This is a typical location, but implementers may use other locations between the MAC SAP and PHY_SAP_TX as long as they provide the specified behavior as observed at LLC, MLME and the WM.

Prepare_MPDU (1,1) /* for STA and AP */

PM_Filter_AP (1,1) /* AP version */
Process Prepare_MPDU

- **Encrypt**
  - Procedure used for WEP encryption.
  - If dot11PrivacyOptionImplemented=false, this procedure is not present.

**Procedure Encrypt**

- **Encrypt**:
  - `encryptLng := length(wpdu) - sMacHdrLng;`
  - `encipher := encrypt_1c(1)`
  - `icv := initCrc` (ICV value calculated from plaintext)
  - `wpdu := insertIVAndKeyId(wpdu, encryptLng)`
  - `wpdu := setWepBit(wpdu, 1)`

- **Test if addr4 field is present.** (Only need at AP)

- **Key lookup**:
  - `keyOn := false`
  - `key := kmap[wekey, kndx] 0` (key if no mapping or group dest.)

- **ICV generation algorithm**: not specified, but use of a new IV for each MPDU is strongly recommended.

**Algorithm for changing dot11WepDefaultKeyId** is not specified. If all stations in the BSS have the same values in the group destination, a station’s DefaultKeyId algorithm does not affect interoperability.

**If mapping keyOn=false, do not encrypt.**

- **Set WEP bit in Frame Control field.**

- **Insert IV and keyId between MAC header and data field.**

- **Use RC4 PRNG to generate an encrypt string as long as the MPDU payload plus the ICV field.**

- **Concatenate key with IV for encryption PRNG seed.**

- **Use default key if no mapping or group dest.**

**if isWds then sWdsAddLng else 0 fi**

**The IV generation algorithm is not specified, but use of a new IV for each MPDU is recommended STRONGLY.**

- **Encrypt by xor of payload with encrypt string.**

- **Encrypt ICV octets and attach to end of MPDU.**

**Encryption by PRNG**

- `newIV := call genIV(x)`

**Error handling**: Return error to LLC if key is null.

- **Return error to LLC if key is null.**
Process PM_Filter_AP

1. **Bss_Cfp**
   - not import (mCfp)

2. **PM_Bss**
   - Pdu_Confirm (fsdu, resl)
     - not fsPend and ((length (cfQ) /= 0) or (length(txQ) /= 0))

3. **resl**
   - fsPend:= false
   - else
     - fsdu:= first(cfQ), cfQ:= tail(cfQ)

*This returns the fsdu to the queue. At the next cf-poll, either the same fsdu or a different fsdu may be selected for transmission.*
This block does octet-level transfers of MPDUs from the MAC to the PHY transmitter, generating FCS fields and inserting timestamp values where necessary. Process Data_Pump begins transmitting when TxRequest arrives. The sender of TxRequest is assumed to have done the appropriate actions prior to transmitting onto the WM. If these actions include performing random backoff or invoking the "backoff procedure" (see 9.2.5.2), a Backoff signal is sent to process Backoff. At the completion of each backoff, a BkDone signal is returned to the sender of the Backoff signal at the correct time to send a TxRequest. The medium state updates (busy, idle, slot) from Channel_State are forwarded to Backoff_Procedure via Data_Pump to prevent decrementing the backoff count while transmitting Cts or Ack frames. This block is used in both station and AP.
This process sends an Mpdu to the Phy while generating & appending the Fcs. On beacons and probe responses inserts (TSF + Phy TxDelay) in the timestamp field at confirm of octet 23.

To transmit after Sifs, send TxRequest at end of the M1 interval (see 9.2.10). For Pifs, Difs, or any backoff slot, TxRequest is sent at the end of the appropriate M2 interval. *
Process Backoff Procedure

No_Backoff

Backoff (cw, cnt)

source :=
sender, mBkIP := true

export (mBkIP)

cnt

(<0) (>=0)

SlotCnt := call Random(cw)

Choose random backoff count if cnt = -1.

At start assume that the WM is busy until receiving a signal which indicates the WM is idle.

Transitions to Channel_Idle also align the Backoff signal arrival time to slot boundary (M2) timing.

Transitions to Channel_Idle also align the Backoff signal arrival time to slot boundary (M2) timing.

Slotonly sent when WM idle. This is for the case where WM idle at arrival of Backoff signal.

Busy

Idle

Slot

Cancel

mBkIP := false

export (mBkIP)

No_Backoff

/* This process performs the Backoff Procedure (see 9.2.5.2), returning Done(-1) when Tx may begin, or Done(n>=0) if cancelled. Backoff(cw,-1) starts new random backoff. Backoff(x,n>=0) resumes cancelled backoff. Backoff(0,0) sends Done(-1) when WM idle. */

/* Input Signal Summary BUSY is sent by Channel_State when the WM changes from idle to busy due to CCA and/or NAV, and by Data_Pump at TxStart. CANCEL is sent by TxCoordination to terminate a backoff and return the residual backoff count value. IDLE is sent by Channel_State at the end of the M2 interval (see 9.2.10) that busy WM has been idle (CCA & NAV) for DIFS (EIFS after Rx error). SLOT is sent by Channel_State at the end of each M2 interval (see 9.2.10) while the WM is idle. Busy, Idle, and Slot are forwarded from Channel_State via Data_Pump when transmit is not in progress. */
Process Backoff_Procedure

1. **Idle**
   - Idle signal not sent if WM free. This consumes any Idles still on input queue.
   - \( \text{slotCnt} = \text{slotCnt} - 1 \)

2. **Slot**
   - Go back and wait for WM to become idle.

3. **Busy**
   - Complete at M2 of proper slot, even if \( \text{slotCnt} = 0 \) at entry to state.
   - \( \text{BkDone} \) (slotCnt)

4. **Cancel**
   - Cancel has priority over other transitions. \( \text{Done}(0) \) returned if Cancel arrives at instant \( \text{slotCnt} = 0 \).
   - \( \text{BkDone} \) (slotCnt) to source

5. **Done**
   - Done sent with value -1 when backoff counts down to zero.

\[ \text{BkDone} \] if \( \text{cnt} = 0 \) then -2

\( \text{BkDone} \) to source
In this block are the MAC MIB and MLME_SAP service primitives described in Clause 10. The MLME services are performed in the MLME block. This block is used both in station and AP. *
This state machine passes indications through, unmodified, from MLME to the MLME SAP. MlmeAssociate.indication and MlmeReassociate.indication are only generated by MLME at APs.

  - IDLE
  - IBSS
  - BSS
  - AP

- **IDLE**
  - **IBSS**
  - **BSS**
  - **AP**
In this block are the handlers for MLME operation requests, the responders for incoming management frames, and the time synchronization function for the AP, as well as contention free period timing if this AP includes a PCF. This block also contains the process which maintains record of power save mode and station state for access by other processes. */
This process records power save state as indicated in the headers of all valid rx frames; and auth/asoc state from all management exchanges by this station.*

Each of these sets holds MAC addresses of stations with a particular operational state. Stations are added to and removed from sets due to MLME requests, received management frames, and bits in received MAC headers. Sets are not aged, as there is no requirement for periodic activity, but aging to expunge addresses of inactive stations is permitted.

/* dcl awake, /* detected in sta_active mode */
   asleep, /* detected in power_save mode */
   authOs, /* authenticated by open system */
   authKey, /* authenticated by any other alg. */
   asoc /* associated (0|1 member, non-AP) */
MacAddrSet ;

ps_mon1a(2)

Clear specific authentication info at startup but not reset.

Clear info on power save and associated stations at startup and at reset.

ResetMAC

Send PsChange when sleeping station reports active mode.

Association adds asoc state while leaving auth info intact.

Deauthenticate of associated station causes disassociate at same time.
Process Power_Save_Monitor

PsInquiry

PsInquiry returns PsResponse to report power mode awake, asleep, or unknown at the target station.

SsInquiry

SsInquiry returns SsResponse to report station state not_auth, assoc, or dis_assoc; and authentication state not_auth, auth_open, or auth_key at the target station.

PsResponse

PsResponse to sender

SsResponse

SsResponse to sender

When there is no association info, station state is identical to authentication state.
/* Each of these ovals represents a SERVICE. Each service contains a DISJOINT SUBSET of the input signal set of this process. Services share local variables and the input queue. At any instant, a state transition can occur in, at most, one service -- the service which handles the kind of signal at the head of the process input queue. */

This service responds to incoming Associate, and Reassociate at the AP, and handles Disassociate requests from Mlme and WM. This service also generates responses for class 3 errors.

When a disassociation request is received, the service verifies the BSSID of the request and updates the station state. If the association is successful, the service sends a class 3 error message and updates the station state. If the association is not successful, the service sends a notification frame and updates the station state.
On this page are responses to associate and reassociate requests. More of this state on previous page.

imported dot11AuthenticationResponse_Timeout Kusec;

A station is allowed to reject an open system auth request with status unspec_fail.

Sst(arSta, auth_open)

arSdu:= mkFrame (auth, arSta, (arAlg // mkOS(2,2) // successful // mkElem(eCtxt, arChalng)))
Send (arSdu, norm)

set(now+ (import(dot11Authentication_Respone_Timeout)), Tchal)

Set response timeout and await response to challenge.

The chKey value used to generate challenge text is arbitrary, and does not need to be shared. However, implementers are advised that the source of chKey SHOULD NOT be one of the WEP keys, because the output of the PRNG when using chKey is sent, unencrypted, in the challenge text field.

* This service handles incoming Authentication & Deauthentication frames.
In the case of undecryptable response, assume Auth frame from expected source is sequence 3.

Timeout while waiting is a failed attempt.

A station is allowed to reject an open system auth request with status unspec_fail.
The selection criteria for Mmpdu Tx data rate are not specified. Frames to group addresses must use one of the basic rates. Requests should use one of the basic rates unless the operational rates of the recipient station are known. Responses must use a basic rate or the rate at which the request was received.

* This process filters valid received frames by destination address, and Bssid for group destination addresses. This process also maintains received pdu counters and the tuple cache for detecting duplicated unicast frames.

Data and management frames which need acknowledgment cause a NeedAck signal to Protocol_Control as well as an RxMpdu to Defragment. Piggybacked CfAcks cause RxCfack signals, and CfPolls cause RxCfpoll signals to Protocol_Control. If an RxCfPoll is sent for a Data+CiPoll or Data+CfPoll+CfAck, the NeedAck has to reach TxCord during the Sifs. (The data frame report cannot serve this purpose because the payload may be a nonfinal fragment.)

Duration and CfP duration remaining are reported to Channel_State, and power save mode is reported to Mlme.*

wep_decrypt_2b(3)

Decryption:

- Decrypt
  - (pdu, icvOk, wMap, sKey_MappingLength, wDefault)

- icvOk: Icv errors and certain undecryptable errors counted in Decrypt procedure.

- icvOk (true):
  - (true)
  - (false)

- icvOk (false):
  - (auth)
  - (true)
  - (false)

- de_frag:
  - Do not report receipt of data frames with Icv errors.
  - Authentication challenge responses with Icv errors are reported, but Decrypt removes payload so Auth service is able to distinguish a bad key from a nonresponse.

- RxIndicate
  - (pdu, endRx, startTs, rxRate)
  - (auth)
  - (true)
  - (false)
defragment_3c(3)

Mpdus is not fragmented or defragmentation is complete.

Intermediate or final Mpdus of fragmented Msdu.

Initial Mpdus of fragmented Msdu. Find free buffer to begin Msdu reception.

icvOk:=
false
If calculated ICV not valid, discard frame, body, and report error.

icvOk:=
true
ICV test correct.

Annex K

(informative)

High Rate PHY/FH interoperability

K.1 Status of this Annex

The mechanisms described in this annex are obsolete. Consequently, this annex may be removed in a future revision of the standard.

K.2 General

The Channel Agility option described in 17.4.6.8 provides for IEEE 802.11 FH PHY interoperability with the High Rate PHY. The FH patterns, as defined within this annex, enable synchronization with an FH-PHY-compliant BSS in North America and most of Europe. In addition, CCA requirements on a High Rate STA using this mode provide for CCA detection of 1 MHz wide FH signals within the wideband DS channel selected. FH PHY STAs operating in mixed mode FH/DS environments are advised to use similar cross PHY CCA mechanisms. The FH (Channel Agility) and cross CCA mechanisms provide the basic mechanisms to enable coexistence and interoperability.

The MAC elements include both DS and FH elements in Beacon frames and Probe Response frames when the Channel Agility option is turned on. Added capability fields indicate the ability to support the Channel Agility option and to indicate whether the option is turned on. These fields allow synchronization to the hopping sequence and timing, identification of what modes are being used within a BSS when joining on either High Rate or FHSS sides, and rejection of an association request in some cases.

Interoperability within an infrastructure BSS can be achieved, as an example, using a virtual dual AP. A virtual dual AP is defined, for purposes of discussion, as two logically separate APs that exist within a single physical AP with a single radio (one transmit and one receive path). Both FHSS and High Rate logical APs send out their own Beacon frames, DTIMs, and other nondirected packets. The two sides interact in the sharing of the medium and the AP’s processor and radio. Addressing and association issues may be handled in one of several ways and are left as an implementation choice.

Minimal interoperability with a nonhopping High Rate or legacy DSSS is provided by the use of a channel at least 1/7 or more of the time. While throughput would be significantly reduced by having a channel only 1/7 of the time, connection and minimal throughput can be provided.

When the FH option is utilized, the HR/DSSS PHY should provide the CCA capability to detect 1 MHz wide FH PHY signals operating within the wideband DS channel at levels 10 dB higher than that specified in 17.4.8.5 for wideband HR/DSSS signals. This is in addition to the primary CCA requirements in 17.4.8.5. A timeout mechanism to avoid excessive deferral to constant CW or other non-IEEE-802.11 type signals is allowed.

FH PHY STAs operating in mixed environments should provide similar CCA mechanisms to detect wideband DSSS signals at levels specified in 17.4.8.5, but measured within a 1 MHz bandwidth. Signal levels measured in a full DSSS channel are generally 10 dB or higher.
Annex L

(informative)

Examples of encoding a frame for OFDM PHYs

L.1 Example 1 - BCC encoding

L.1.1 Introduction

The purpose of this annex is to show an example of encoding a frame for the OFDM PHY, as described in Clause 18. This example covers all the encoding details defined by this standard.

The encoding illustration goes through the following stages:

a) Generating the short training sequence section of the preamble;
b) Generating the long preamble sequence section of the preamble;
c) Generating the SIGNAL field bits;
d) Coding and interleaving the SIGNAL field bits;
e) Mapping the SIGNAL field into frequency domain;
f) Pilot insertion;
g) Transforming into time domain;
h) Delineating the data octet stream into a bit stream;
i) Prepending the SERVICE field and adding the pad bits, thus forming the DATA;
j) Scrambling and zeroing the tail bits;
k) Encoding the DATA with a convolutional encoder and puncturing;
l) Mapping into complex 16-QAM symbols;
m) Pilot insertion;
n) Transforming from frequency to time and adding a circular prefix;
o) Concatenating the OFDM symbols into a single, time-domain signal.

In the description of time domain waveforms, a complex baseband signal at 20 Msample/s shall be used.

This example uses the 36 Mb/s data rate and a message of 100 octets. These parameters are chosen in order to illustrate as many nontrivial aspects of the processing as possible:

— Use of several bits per symbol (4 in this case);
— Puncturing of the convolutional code;
— Interleaving, which uses the LSB–MSB swapping stage;
— Scrambling of the pilot subcarriers.

In each Annex L table that has "Binary Val" columns, the bit positions of the binary values are specified in the header of the table.
L.1.2 The message for the BCC example

The message being encoded consists of the first 72 characters (shown in **bold** and including line breaks) of the well-known “Ode to Joy” by F. Schiller:

*Joy, bright spark of divinity,*  
*Daughter of Elysium,*  
*Fire-insired we tread*  
*Thy sanctuary.*  
*Thy magic power re-unites*  
*All that custom has divided,*  
*All men become brothers*  
*Under the sway of thy gentle wings.*

The message is converted to ASCII; then it is prepended with an appropriate MAC header and a CRC32 is added. The resulting 100 octets PSDU is shown in Table L-1.

The single period of the short training sequence is extended periodically for 161 samples (about 8 μs), and then multiplied by the window function:

\[
W(k) = \begin{cases} 
0.5 & k = 0 \\
1 & 1 \leq k \leq 159 \\
0.5 & k = 160
\end{cases}
\]

The last sample serves as an overlap with the following OFDM symbol. The 161 samples vector is shown in Table L-4. The time-windowing feature illustrated here is not part of the normative specifications.

</tbody>
</table>

The time domain representation is derived by performing IFFT on the contents of Table L-5, cyclically extending the result to get the cyclic prefix, and then multiplying with the window function given in L.1.3.1. The resulting 161 points vector is shown in Table L-6. The samples are appended to the short sequence section by overlapping and adding element 160 of Table L-4 to element 0 of Table L-6.

L.1.4 Generation of the SIGNAL field

L.1.4.1 SIGNAL field bit assignment

The SIGNAL field bit assignment follows 18.3.4 and Figure 18-5. The transmitted bits are shown in Table L-7, where bit 0 is transmitted first.

L.1.4.4 SIGNAL field frequency domain

The encoded and interleaved bits are BPSK modulated to yield the frequency domain representation given in Table L-10. Locations –21, –7, 7, and 21 are skipped and are used for pilot insertion.
Four pilot subcarriers are added by taking the values \(\{1,0,1,0,1,0,\ldots,1,0\}\), multiplying them by the first element of sequence \(p_0\ldots p_{126}\), given in Equation (18-22) (in 18.3.5.10), and inserting them into location \(\{-21,-7,7,21\}\), respectively. The resulting frequency domain values are given in Table L-11.

L.1.4.5 SIGNAL field time domain

The time domain representation is derived by performing IFFT on the contents of Table L-11, extending cyclically, and multiplying by the window function

\[ W(k) = \begin{cases} 
0.5 & k = 0 \\
1 & 1 \leq k \leq 79 \\
0.5 & k = 80 
\end{cases} \]

The resulting 81 samples vector is shown in Table L-12. Note that the time-windowing feature illustrated here is not a part of the normative specifications.

The SIGNAL field samples are appended with one sample overlap to the preamble, given in Table L-6.

L.1.5 Generating the DATA bits for the BCC example

L.1.5.1 Delineating, SERVICE field prepending, and zero padding

The transmitted message shown in Table L-1 contains 100 octets or, equivalently, 800 bits. The bits are prepended by the 16 SERVICE field bits and are appended by 6 tail bits. The resulting 822 bits are appended by some number of bits with value 0 to yield an integral number of OFDM symbols. For the 36 Mb/s mode, there are 144 data bits per OFDM symbol; the overall number of bits is Ceiling (822/144) × 144 = 864. Hence, 864 – 822 = 42 zero bits are appended.

The DATA bits are shown in Table L-13.

**L.1.5.2 Scrambling the BCC example**

The 864 bits are scrambled by the scrambler defined in 18.3.5.5. The initial state of the scrambler is the state 1011101. The generated scrambling sequence is given in Table L-14.
After scrambling, the 6 bits in location 816 (i.e., bit 817) to 821 (i.e., bit 822) are set to 0. The scrambled DATA bits are shown in Table L-15.

L.1.6 Generating the first DATA symbol for the BCC example

L.1.6.1 Coding the DATA bits

The scrambled bits are coded with a rate $3/4$ convolutional code. The DATA encoded bits are shown in Table L-16.

L.1.6.2 Interleaving the DATA bits

The interleaver is defined as a two-permutation process. The index of the coded bit before the first permutation shall be denoted by \( k \); \( i \) shall be the index after the first and before the second permutation; and \( j \) shall be the index after the second permutation, just prior to modulation mapping. The mapping from \( k \) to \( i \) is shown in Table L-17, and the mapping from \( i \) to \( j \) is shown in Table L-18.

As a specific example, consider the case of \( k = 17 \) (the 18th bit after encoding and puncturing). It is mapped by the first permutation to \( i = 13 \) and by the second permutation to \( j = 12 \) (the 13th bit before mapping).

L.1.6.3 Mapping into symbols

The frequency domain symbols are generated by grouping 4 coded bits and mapping into complex 16-QAM symbols according to Table 18-10 (in 18.3.5.8). For instance, the first 4 bits (0 1 1 1) are mapped to the complex value, $-0.316 + 0.316j$, inserted at subcarrier #26.

Four pilot subcarriers are added by taking the values $\{1.0, 1.0, 1.0, -1.0\}$, multiplying them by the second element of sequence p, given in Equation (18-22) (in 18.3.5.10), and inserting them into location $\{-21, -7, 7, 21\}$, respectively.

The frequency domain is shown in Table L-20.

</tbody>
</table>
The time domain samples are produced by performing IFFT, cyclically extending, and multiplying with the window function in the same manner as described in L.1.4.5. The time domain samples are appended with one sample overlap to the SIGNAL field symbol.

**L.1.7 Generating the additional DATA symbols**

The generation of the additional five data symbols follows the same procedure as described in Clause 4. Special attention should be paid to the scrambling of the pilot subcarriers. Table L-21 lists the polarity of the pilot subcarriers and the elements of the sequence \( p_0 \ldots p_{126} \) for the DATA symbols. For completeness, the pilots in the SIGNAL are included as well. The symbols are appended one after the other with a one-sample overlap.

**Table L-21—Polarity of the pilot subcarriers**

**L.1.8 The entire packet for the BCC example**

The packet in its entirety is shown in the tables in this subclause. These tables illustrate the short training sequence section (Table L-22), the long training sequence section (Table L-23), the SIGNAL field...
(Table L-24), and the six DATA symbols (Table L-25 to Table L-30).

L.2 Generating encoded DATA bits—LDPC example 1

LDPC example 1 is similar to the BCC example. This example illustrates LDPC shortening, encoding, and puncturing of a single codeword.

Input TXVECTOR parameters for LDPC example 1:
- FEC_CODING = LDPC_CODING = 1 (LDPC encoder; not BCC)
- CH_BANDWIDTH = HT_CBW20 = 0 (CH_BANDWIDTH = 0 => 20 MHz)
- MCS = 4 (MCS = 4; QAM 16; Coding rate = 3/4)
- Coding rate R = 3/4
- LENGTH = 100 octets (with 16-bit SERVICE field becomes 102 Octets = 816 bits to scramble and encode)
- STBC = 0 (STBC = 0 => OFF; m_STBC=1)

L.2.1 The message for LDPC example 1

The message being encoded consists of the first 72 characters (shown in bold and including line breaks) of the well-known “Ode to Joy” by F. Schiller:

Joy, bright spark of divinity,
Daughter of Elysium,
Fire-insired we tread
Thy sanctuary.
Thy magic power re-unites
All that custom has divided,
All men become brothers
Under the sway of thy gentle wings.

The message is converted to ASCII; then it is prepended with an appropriate MAC header, and a CRC32 is added. The resulting 100 octets PSDU is shown in Table L-31.

NOTE 1—The message for LDPC example 1 is identical to the message for the BCC example; in other words, the FCS field (octets 97–100) has the same CRC 32 value.

NOTE 2—The DurationID field (i.e., octets 3 and 4) remains 0x02E = 46 µs.

L.2.2 Prepending the SERVICE field for LDPC example 1

The transmitted message shown in Table L-31 contains 100 octets, or equivalently, 800 bits. The bits are prepended by the 16 SERVICE field bits (bits 0–15 in Table L-32), as defined in 20.3.11.2, but tail bits and padding bits are not appended as in the BCC example. The resulting 816 bits are shown in Table L-32.

</table>
The 816 bits are scrambled by the scrambler defined in 18.3.5.5. The initial state of the scrambler is the state 1011101 binary (0x5D hexadecimal). The scrambled sequence is given in Table L-33.

NOTE—The scrambled entries for the correct CRC32 value are given in bits 784–815.

The equations of 20.3.11.7.5 are solved to calculate the following derived parameters for LDPC example 1 from the input TXVECTOR parameters:

- \( N_{CW} = 1 \) (number of codewords)
- \( L_{LDPC} = 1944 \) (size of codeword)
- \( N_{CBPS} = 208 \) (number of coded bits per symbol)
- \( N_{avbits} = 1248 \) (number of available bits)
- \( N_{\text{shrt}} = 642 \) (number of bits to be shortened)
- \( N_{\text{punc}} = 54 \) (number of bits to be punctured)
- \( N_{SYM} = 6 \) (number of OFDM symbols)
- \( N_{\text{rep}} = 0 \) (number of bits to be repeated)

The results of applying shortening bits, as prescribed in paragraph (c) of 20.3.11.7.5, is given in Table L-34.

L.2.5 Encoding data for LDPC example 1

The DATA with shortening bits are LDPC encoded as a single \( N_{\text{chip}} = 1 \) codeword \( L_{\text{LDPC}} = 944; R = 3/4 \) as prescribed by paragraph (c) of 20.3.11.7.5. The results are given in Table L-35.

NOTE—The LDPC encoder appends 486 bits (i.e., bits 1458–1943) after the shortening bits.

L.2.6 Removing shortening bits and puncturing for LDPC example 1

The shortening bits, applied before LDPC encoding, are now removed as prescribed in paragraph (c) of 20.3.11.7.5. Finally, either puncturing is applied as described in paragraph (d) of the same subclause, or the copying of repeated bits is applied as described in paragraph (e) of the same subclause. In LDPC example 1, because $N_{punc} = 54$ is nonzero and $N_{rep} = 0$, puncturing is prescribed and completes the LDPC encoding process.

The results are given in Table L-36.

NOTE—The $N_{shrt} = 642$ shortening bits have been removed, and the $N_{punc} = 54$ bits have been punctured from Table L-35 to produce bits 816–1247 of Table L-36.

L.3 Generating encoded DATA bits—LDPC example 2

LDPC example 2 exercises the alternative branches of the LDPC encoding procedure not exercised in LDPC example 1. Example 2 also exhibits LDPC shortening, encoding, and padding by repetition and employs multiple codewords and diversifies the TXVECTOR parameters—all without making the length of this example cumbersome.

The length of the text of the message is increased by 40 octets, from 72 characters to 112 characters, in order to illustrate padding (rather than puncturing) and encoding of multiple codewords.

Input TXVECTOR parameters for LDPC example 2:
- FEC_CODING = LDPC_CODING = 1 (LDPC encoder; not BCC)
- CH_BANDWIDTH = HT_CBW40 = 1 (CH_BANDWIDTH = 1 => 40 MHz)
- MCS = 1 (MCS = 1; QPSK; coding rate = 1/2)
- Coding rate R = 1/2
- LENGTH = 140 octets (with 16-bit SERVICE field becomes 142 octets = 1136 bits to scramble and encode)
- STBC = 1 (STBC = 1 => ON; m_STBC = 2)

L.3.1 The message for LDPC example 2

The message being encoded consists of the first 112 characters (shown in bold and including line breaks) of the well-known “Ode to Joy” by F. Schiller:

Joy, bright spark of divinity,
Daughter of Elysium,
Fire-insired we tread
Thy sanctuary.
Thy magic power re-unites
All that custom has divided,
All men become brothers
Under the sway of thy gentle wings.

The message is converted to ASCII; then it is prepended with an appropriate MAC header and a CRC32 is added. The resulting 140 octets PSDU is shown in Table L-37.

Because of the additional 40 characters, note that the message for LDPC example 2 has a different FCS field (octets 137–140) than the previous examples and that the DurationID field (i.e., octets 3 and 4) changes to 0x036 = 54 µs.

L.3.2 Prepending the SERVICE field for LDPC example 2

The transmitted message shown in Table L-37 contains 140 octets, or equivalently, 1120 bits. The bits are prepended by the 16 SERVICE field bits (bits 0–15 in Table L-38), as defined by 20.3.11.2, but tail bits and padding bits are not appended as in the BCC example. The resulting 1136 bits are shown in Table L-38.

The 1136 bits are scrambled by the scrambler defined in 18.3.5.5. The initial state of the scrambler is the state 1011101 binary (0x5D hexadecimal). The scrambled sequence is given in Table L-39.

**L.3.3 Scrambling LDPC example 2**

The 1136 bits are scrambled by the scrambler defined in 18.3.5.5. The initial state of the scrambler is the state 1011101 binary (0x5D hexadecimal). The scrambled sequence is given in Table L-39.

The equations of 20.3.11.7.5 are solved to calculate the following derived parameters for LDPC example 2 from the input TXVECTOR parameters:

- $N_{CW} = 2$ (number of codewords)
- $L_{LDPC} = 1296$ (size of codeword)
- $N_{CBPS} = 216$ (number of coded bits per symbol)
- $N_{avbits} = 2592$ (number of available bits)
- $N_{shrt} = 160$ (number of bits to be shortened)
- $N_{punc} = 0$ (number of bits to be punctured)
- $N_{SYM} = 12$ (number of OFDM symbols)
- $N_{rep} = 160$ (number of bits to be repeated)
The results of applying shortening bits, as prescribed in paragraph (c) of 20.3.11.7.5, is given in Table L-40.

NOTE—\( N_{\text{shrt}} = 160 \) shortening bits have been inserted as 0s: 80 zeros at bits 568–647 and 80 zeros at bits 1216–1295; this order equally distributes the shortening bits across the \( N_{\text{CIF}} = 2 \) codewords.

L.3.5 Encoding the data for LDPC example 2

The DATA with shortening bits are LDPC encoded as two (NCW = 2) codewords (L_{LDPC} = 1296; R = 1/2) as prescribed by paragraph (c) of 20.3.11.7.5. The results are given in Table L-41.

NOTE—The LDPC encoder appends 648 bits as follows: bits 648–1295 after the first shortened codeword and another 648 bits (bits 1944–2591) after the second shortened codeword.

<table>

</table>
L.3.6 Removing shortening bits and repetition for LDPC example 2

The shortening bits, applied before LDPC encoding, are now removed as prescribed in paragraph (c) of 20.3.11.7.5. Finally, either puncturing is applied as described in paragraph (d) of the same subclause, or the copying of repeated bits is applied as described in paragraph (e) of the same subclause. In LDPC example 2, because \( N_{\text{punc}} = 0 \) and \( N_{\text{rep}} = 160 \) are nonzero, repetition is prescribed and completes the LDPC encoding process.

The results are given in Table L-42.

NOTE—The first 80 shortening bits (bits 568–647 from Table L-41) have been removed from the first codeword between bits 567 and 568 of Table L-42, and the second 80 shortening bits (bits 1864–1943 of Table L-41) have been removed between bits 1215 and 1216 of Table L-42. Also, 80 bits have been repeated from the beginning of the first codeword (bits 0–79) to the end of the first codeword (bits 1216–1295), and 80 bits have been repeated from the beginning of the second codeword (bits 1296–1375) to end of the second codeword (bits 2512–2591) in Table L-42.

******************************************************************************
* Routine: SanityCheckTable -- verify Sbox properties
* *
* Inputs:   Sbox
* Output:   None, but an assertion fails if the tables are wrong
* Notes:    * The purpose of this routine is solely to illustrate and

Copyright © 2012 IEEE. All rights reserved.
verify the following properties of the Sbox table:
- the Sbox is a "2x2" subset of the AES table:
  Sbox + affine transform + MDS.
- the Sbox table can be easily designed to fit in a
  512-byte table, using a byte swap
- the Sbox table can be easily designed to fit in a
  256-byte table, using some shifts and a byte swap

```
void SanityCheckTable(void)
{
    const static int  M_x = 0x11B;   /* AES irreducible polynomial */
    const static byte Sbox8[256] = {

/*************************************************************************/
/* Routine: Phase 1 -- generate P1K, given TA, TK, IV32 */
/*************************************************************************/
* Inputs:
*   TK[] = Temporal Key [128 bits]
*   TA[] = transmitter's MAC address [ 48 bits]
*   IV32 = upper 32 bits of IV [ 32 bits]
* Output:
*   P1K[] = Phase 1 key [ 80 bits]
* Note:
*   This function only needs to be called every 2**16 frames,
*   although in theory it could be called every frame.
*************************************************************************/
```
void Phase1(u16b *P1K, const byte *TK, const byte *TA, u32b IV32)
{
    int i;

    /* Initialize the 80 bits of P1K[] from IV32 and TA[0..5] */
    P1K[0] = Lo16(IV32);
    P1K[1] = Hi16(IV32);
    P1K[2] = Mk16(TA[1], TA[0]); /* use TA[] as little-endian */
    P1K[3] = Mk16(TA[3], TA[2]);
    P1K[4] = Mk16(TA[5], TA[4]);

    /* Now compute an unbalanced Feistel cipher with 80-bit block */
    /* size on the 80-bit block P1K[], using the 128-bit key TK[] */
    for (i = 0; i < PHASE1_LOOP_CNT; i++)
    {
        /* Each add operation here is mod 2**16 */
        P1K[0] += _S_(P1K[4] ^ TK16((i&1)+0));
        P1K[1] += _S_(P1K[0] ^ TK16((i&1)+2));
        P1K[4] += i; /* avoid "slide attacks" */
    }
}

.stopPropagation();

*******************************************************************************
* Routine: Phase 2 -- generate ARC4KEY, given TK, P1K, IV16
*
* Inputs:
*   TK[]  = Temporal Key [128 bits]
*   P1K[] = Phase 1 output key [80 bits]
*   IV16  = low 16 bits of IV counter [16 bits]
* Output:
*   ARC4KEY[] = the key used to encrypt the frame [128 bits]
*
* Note:
*   The value {TA,IV32,IV16} for Phase1/Phase2 must be unique
*   across all frames using the same key TK value. Then, for a
*   given value of TK[], this TKIP48 construction guarantees that
*   the final ARC4KEY value is unique across all frames.
*
* Suggested implementation optimization: if PPK[] is "overlaid"
* appropriately on ARC4KEY[], there is no need for the final
* for loop below that copies the PPK[] result into ARC4KEY[].
*
void Phase2(byte *ARC4KEY, const byte *TK, const u16b *P1K, u16b IV16)
{
    int i;
    u16b PPK[6]; /* temporary key for mixing */

M.2 Michael reference implementation and test vectors

M.2.1 Michael test vectors

M.2.1.1 Introduction

To ensure correct implementation of Michael, here are some test vectors. These test vectors still have to be confirmed by an independent implementation.

M.2.1.2 Block function

Table M-1 gives some test vectors for the block function.

<table>
<thead>
<tr>
<th>Input</th>
<th># times</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>(00000000, 00000000)</td>
<td>1</td>
<td>(00000000, 00000000)</td>
</tr>
<tr>
<td>(00000000, 00000001)</td>
<td>1</td>
<td>(c00015a8, c0000b95)</td>
</tr>
<tr>
<td>(00000001, 00000000)</td>
<td>1</td>
<td>(6b519593, 5728b8b8a)</td>
</tr>
<tr>
<td>(01234567, 83659326)</td>
<td>1</td>
<td>(441492c2, 1d8427ed)</td>
</tr>
<tr>
<td>(00000001, 00000000)</td>
<td>1000</td>
<td>(9f04c4ad, 2ec6c2bf)</td>
</tr>
</tbody>
</table>

The first four rows give test vectors for a single application of the block function $b$. The last row gives a test vector for 1000 repeated applications of the block function. Together these should provide adequate test coverage.

M.2.1.3 Michael

Table M-2 gives some test vectors for Michael.

<table>
<thead>
<tr>
<th>Key</th>
<th>Message</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000000000000000000000</td>
<td>&quot;&quot;</td>
<td>82925c1ca1d130b8</td>
</tr>
<tr>
<td>82925c1ca1d130b8</td>
<td>&quot;M&quot;</td>
<td>434721ca40639b3f</td>
</tr>
<tr>
<td>434721ca40639b3f</td>
<td>&quot;Mi &quot;</td>
<td>e8f9becae97e5d29</td>
</tr>
<tr>
<td>E8f9becae97e5d29</td>
<td>&quot;Mic&quot;</td>
<td>90038fc6cf13c1db</td>
</tr>
</tbody>
</table>
Note that each key is the result of the previous line, which makes it easy to construct a single test out of all of these test cases.

**M.2.2 Sample code for Michael**

```cpp
//
// Michael.h    Reference implementation for Michael
//
// A Michael object implements the computation of the MIC.
// Conceptually, the object stores the message to be authenticated.
// At construction the message is empty.
// The append() method appends bytes to the message.
// The getMic() method computes the MIC over the message and returns the result.
// As a side-effect it also resets the stored message
to the empty message so that the object can be reused
for another MIC computation.

class Michael
{

public:
    // Constructor requires a pointer to 8 bytes of key
    Michael( Byte * key );

    // Destructor
    ~Michael();

    // Clear the internal message,
    // resets the object to the state just after construction.
    void clear();

    // Set the key to a new value
    void setKey( Byte * key );

    // Append bytes to the message to be MICed
```
void append( Byte * src, int nBytes );

// Get the MIC result. Destination should accept 8 bytes of result.
// This also resets the message to empty.
void getMIC( Byte * dst );

// Run the test plan to verify proper operations

M.4 Suggested pass-phrase-to-PSK mapping

M.4.1 Introduction

The RSNA PSK consists of 256 bits, or 64 octets when represented in hex. It is difficult for a user to correctly enter 64 hex characters. Most users, however, are familiar with passwords and pass-phrases and feel more comfortable entering them than entering keys. A user is more likely to be able to enter an ASCII password or pass-phrase, even though doing so limits the set of possible keys. This suggests that the best that can be done is to introduce a pass-phrase to PSK mapping.
This subclause defines a pass-phrase–to–PSK mapping that is the recommended practice for use with RSNAs. This pass-phrase mapping was introduced to encourage users unfamiliar with cryptographic concepts to enable the security features of their WLAN.

Keys derived from the pass phrase provide relatively low levels of security, especially with keys generated from short passwords, since they are subject to dictionary attack. Use of the key hash is recommended only where it is impractical to make use of a stronger form of user authentication. A key generated from a pass-phrase of less than about 20 characters is unlikely to deter attacks.

The pass-phrase mapping defined in this subclause uses the PBKDF2 method from PKCS #5 v2.0 [B53].

\[
PSK = PBKDF2(\text{PassPhrase}, \ ssid, \ ssid\text{Length}, \ 4096, \ 256)
\]

Here, the following assumptions apply:

- A pass-phrase is a sequence of between 8 and 63 ASCII-encoded characters. The limit of 63 comes from the desire to distinguish between a pass-phrase and a PSK displayed as 64 hexadecimal characters.
- Each character in the pass-phrase must have an encoding in the range of 32 to 126 (decimal), inclusive.
- ssid is the SSID of the ESS or IBSS where this pass-phrase is in use, encoded as an octet string used in the Beacon and Probe Response frames for the ESS or IBSS.
- ssidLength is the number of octets of the ssid.
- 4096 is the number of times the pass-phrase is hashed.
- 256 is the number of bits output by the pass-phrase mapping.

### M.4.2 Reference implementation

```c
/*
* F(P, S, c, i) = U1 xor U2 xor ... Uc
* U1 = PRF(P, S || Int(i))
* U2 = PRF(P, U1)
* Uc = PRF(P, Uc-1)
*/

void F(
    char *password,
    unsigned char *ssid,
    int ssidlength,
    int iterations,
    int count,
    unsigned char *output)
{
    unsigned char digest[36], digest1[A_SHA_DIGEST_LEN];
    int i, j;

    for (i = 0; i < strlen(password); i++) {
        assert((password[i] >= 32) && (password[i] <= 126));
    }
```

/ * U1 = PRF(P, S || int(i)) */
memcpy(digest, ssid, ssidlength);
digest[ssidlength] = (unsigned char)((count>>24) & 0xff);
digest[ssidlength+1] = (unsigned char)((count>>16) & 0xff);
digest[ssidlength+2] = (unsigned char)((count>>8) & 0xff);
digest[ssidlength+3] = (unsigned char)(count & 0xff);
hmac_sha1(digest, ssidlength+4, (unsigned char*) password,
        (int) strlen(password), digest, digest1);

/* output = U1 */
memcpy(output, digest1, A_SHA_DIGEST_LEN);

for (i = 1; i < iterations; i++) {
    /* Un = PRF(P, Un-1) */
hmac_sha1(digest1, A_SHA_DIGEST_LEN, (unsigned char*) password,
            (int) strlen(password), digest);
    memcpy(digest1, digest, A_SHA_DIGEST_LEN);
    /* output = output xor Un */
    for (j = 0; j < A_SHA_DIGEST_LEN; j++) {
        output[j] ^= digest[j];
    }
}

int PasswordHash (char *password,
        unsigned char *ssid,
        int ssidlength,
        unsigned char *output)
{
    if ((strlen(password) > 63) || (ssidlength > 32))
        return 0;

    F(password, ssid, ssidlength, 4096, 1, output);
    F(password, ssid, ssidlength, 4096, 2,
        &output[A_SHA_DIGEST_LEN]);
    return 1;
}

/* password - ascii string up to 63 characters in length */
/* ssid - octet string up to 32 octets */
/* ssidlength - length of ssid in octets */
/* output must be 40 octets in length and outputs 256 bits of key */

M.5 Suggestions for random number generation

M.5.1 General

In order to properly implement cryptographic protocols, every platform needs the ability to generate cryptographic-quality random numbers. IETF RFC 4086 explains the notion of cryptographic-quality random numbers and provides advice on ways to harvest suitable randomness. It recommends sampling multiple sources, each of which contains some randomness, and by passing the complete set of samples through a PRF. By following this advice, an implementation can usually collect enough randomness to distill into a seed for a PRNG whose output is unpredictable.

This clause suggests two sample techniques that can be combined with the other recommendations of IETF RFC 4086 to harvest randomness. The first method is a software solution that can be implemented on most hardware; the second is a hardware-assisted solution. These solutions are expository only, to demonstrate that it is feasible to harvest randomness on any IEEE 802.11 platform. They are not mutually exclusive, and they do not preclude the use of other sources of randomness when available, such as a noisy diode in a power circuit; in this case, the more the merrier. As many sources of randomness as possible should be gathered into a buffer, and then hashed, to obtain a seed for the PRNG.

M.5.2 Software sampling

Due to the nature of clock circuits in modern electronics, there is some lack of correlation between two clocks in two different pieces of equipment, even when high-quality crystals are used—crystal clocks are subject to jitter, noise, drift, and frequency mismatch. This randomness may be as little as the placement of the clock waveform edges. Even if one entity were to attempt to synchronize itself to another entity’s clock, the correlation cannot be perfect due to noise and uncertainties of the synchronization.

Two clock circuits in the same piece of equipment may synchronize in frequency, but again the correlation is not perfect due to the noise and jitter of the circuits.

The randomness between the two clocks may not be much per sample—a tenth of a bit or less—but enough samples may be collected to gather enough randomness to form a seed.
A device can use software methods to take advantage of this lack of synchronization, to collect randomness from different sources. As an example, an AP might measure the frame arrival times on Ethernet wireless ports. There is always some amount of traffic on modern Ethernets: ARPs, DHCP requests, NetBIOS advertisements, etc. The sample algorithm in this subclause uses this traffic. In the example, an AP obtains randomness from the available traffic. If Ethernet traffic is available, the AP utilizes that for a source of randomness. Otherwise, it waits for the first association and creates traffic from which it can obtain randomness.

The clocks used to time the frames should be the highest resolution available, preferably 1 ms resolution or better. The clock used to time frame arrival should not be related to the clock used for frame serialization.

Initialize result to empty array
LoopCounter = 0
Wait until Ethernet traffic or association
Repeat until global key counter "random enough" or 32 times {
  result = PRF-256(0, "Init Counter", Local Mac Address || Time || result || LoopCounter)
  LoopCounter++
  Repeat 32 times {
    If Ethernet traffic available then {
      Take least significant octet of the timestamp when Ethernet packet is received
      Concatenate this octet onto result
    } else {
      Start 4-Way Handshake; after receipt of Message 2, deauthenticate
      Take least significant octet of the timestamp of when Message 1 is sent
      Take least significant octet of the timestamp of when Message 2 is received
      Take the least significant octet of RSSI from Message 2
      Take SNonce from Message 2
      Concatenate the sent time, received time, RSSI and SNonce octets onto result
    }
  }
  Global key counter = result = PRF-256(0, "Init Counter", Local Mac Address || Time || result || LoopCounter)
}

NOTE—The Time is set to 0 if it is not available.

**M.5.3 Hardware-assisted solution**

The sample implementation in this subclause uses hardware ring oscillators to generate randomness, as depicted in Figure M-1.

The circuit in Figure M-1 generates randomness. The clock input should be about the same frequency as the ring oscillator’s natural frequencies. The LFSR should be chosen to be one that is maximal length. Sample LFSRs can be found in Arazi [B6].

The three ring oscillators should be isolated from each other as much as possible to avoid harmonic locking between them. In addition, the three ring oscillators should not be near any other clock circuitry within the system to avoid these ring oscillators’ locking to system clocks. The oscillators should be tested to ensure that their output is not correlated.
The output of the LFSR is read by software and concatenated until enough randomness is collected. As a rule of thumb, reading from the LFSR 8 to 16 times the number of bits as the desired number of random bits is sufficient.

Initialize result to empty array
Repeat 1024 times {
    Read LFSR
    result = result | LFSR
    Wait a time period
}
Global key counter = PRF-256(0, "Init Counter", result)

M.6 Additional test vectors

M.6.1 Notation

In the examples that follow in M.6, frames are represented as a stream of octets, each octet in hex notation, sometimes with text annotation. The order of transmission for octets is left to right, top to bottom. For example, consider the following representation of a frame in Table M-3.
The frame consists of 9 octets, represented in hex notation as “00”, “01”, ..., “08”. The octet represented by “00” is transmitted first, and the octet represented by “08” is transmitted last. Similar tables are used for other purposes, such as describing a cryptographic operation.

In the text discussion outside of tables, integer values are represented in either hex notation using a “0x” prefix or in decimal notation using no prefix. For example, the hex notation 0x12345 and the decimal notation 74565 represent the same integer value.

M.6.2 WEP cryptographic encapsulation

The discussion in this subclause represents an ARC4 encryption using a table that shows the key, plaintext input, and cipher text output. The MPDU data, prior to WEP cryptographic encapsulation, is shown in Table M-4.

<table>

</tr>
</tbody>
</table>

The plaintext consists of the MPDU data, followed by a 4-octet CRC-32 calculated over the MPDU data.

The expanded MPDU, after WEP cryptographic encapsulation, is shown in Table M-6.
The IV consists of the first 3 octets of the ARC4 key, followed by an octet containing the Key ID value in the upper 2 bits. In this example, the Key ID value is 2. The MPDU data consists of the cipher text, excluding the last 4 octets. The ICV consists of the last 4 octets of the cipher text, which is the encrypted CRC-32 value.

**M.6.3 TKIP test vector**

An example of a TKIP MSDU is provided in Table M-7 and Table M-8. The key and PN are used to create the IV, Phase1, and Phase2 keys.

M.7 Key hierarchy test vectors for pairwise keys

M.7.1 General

The test vectors in this subclause provide an example of PTK derivation for both CCMP and TKIP.

Pairwise keys are derived from the PMK, AA, SPA, SNonce, and ANonce. The values in Table M-13 are used as input to the pairwise key derivation test vectors.

M.7.2 CCMP pairwise key derivation

Using the values from Table M-13 for PMK, AA, SPA, SNonce, and ANonce, the key derivation process for CCMP generates a temporal key as shown in Table M-14.

Admission control

N.1 Example use of TSPEC for admission control

Admission control, in general, depends on vendors’ implementations of schedulers, available channel capacity, link conditions, retransmission limits, and the scheduling requirements of a given TSPEC. However, for any given channel capacity, link conditions, and retransmission limits, some TSPEC constructions might be categorically rejected because a scheduler cannot create a meaningful schedule for that TSPEC. There must, for example, be a minimum number of specified fields in the TSPEC in order for the admission control mechanism to create a valid TSPEC. Table N-1 below lists the valid TSPEC parameters that must be present for all admission control algorithms to admit a TSPEC. This represents a set of necessary parameters in order for TSPEC to be admitted; it is not sufficient in and of itself to guarantee TSPEC admittance, which depends upon channel conditions and other factors. Such TSPECs are said to be admissible. In the table, S means specified, X means unspecified, and DC means “do not care.”

N.2 Recommended practices for contention-based admission control

N.2.1 Use of ACM (admission control mandatory) subfield

It is recommended that admission control not be required for the access categories AC_BE and AC_BK. The ACM subfield for these categories should be set to 0. The AC parameters chosen by the AP should account for unadmitted traffic in these ACs.

When dot11SSPNInterfaceActivated is true, it is recommended that any STA authenticated through an SSPN interface use admission control to access categories AC_VO and AC_VI to ensure network utilization consistent with the policy imposed by the SSPN for admission. AC parameters chosen by the AP should further account for any unadmitted traffic in AC_VO and AC_VI that may be reserved for users of a particular SSPN.

N.2.2 Deriving medium time

It is recommended that the AP use the following procedure to derive medium time in its ADDTS Response frame:

There are two requirements to consider: the traffic requirements of the application and the expected error performance of the medium. The application requirements are captured by two TSPEC parameters: Nominal MSDU Size and Mean Data Rate. The medium requirements are captured by two TSPEC parameters: Surplus Bandwidth Allowance and Minimum PHY Rate. The following formula describes how medium time can be calculated (assuming RTS/CTS protection is not used):

\[
\text{Medium Time} = \text{Surplus Bandwidth Allowance} \times \text{pps} \times \text{MPDUExchangeTime}
\]

where:
\[
\text{pps} = \text{Ceiling}(\ (\text{Mean Data Rate} / 8) / \text{Nominal MSDU Size})
\]
\[
\text{MPDUExchangeTime} = \text{duration}(\text{Nominal MSDU Size, Minimum PHY Rate}) + \text{SIFS} + \text{ACK duration}
\]

(see the definition of MPDUExchangeTime in 9.19.4.2.3)

duration() is the PLME-TXTIME primitive that returns the duration of a packet based on its payload size and the PHY data rate employed.

N.3 Guidelines and reference design for sample scheduler and admission control unit

N.3.1 Guidelines for deriving service schedule parameters

The HC establishes the SI for each admitted TS for a STA to derive the aggregate minimum SI contained in the STA’s service schedule. The SI for each TS is equal to a nonzero minimum SI contained in the TSPEC, if it exists; otherwise, it is the nominal MSDU size divided by the mean data rate. The SI contained in the service schedule is equal to the smallest SI for any TSPEC.

The HC can use an aggregate “token bucket specification” to police a STA’s admitted flows. The HC must derive the aggregate mean data rate and aggregate burst size to establish the aggregate token bucket specification. The aggregate mean data rate is equal to the sum of the mean data rates of all of the STA’s admitted TSs. The aggregate burst size is equal to the sum of the burst size of all of the STA’s admitted TSs. An aggregate token bucket is initialized with the aggregate burst size. Tokens are added to the token bucket at the aggregate mean data rate.

When dot11SSPNInterfaceActivated is true, the HC polices all traffic flows from a non-AP STA authenticated against the maximum authorized data rates stored in the dot11InterworkingTable. Each SSPN-authenticated STA is given a maximum bandwidth allowance by the SSPN for each access category as well as scheduled access. The AP polices the SSPN-authenticated STA traffic flows to the maximum bandwidth allowance provided by the SSPN.

N.3.2 TSPEC construction

TSPECs are constructed at the SME from application requirements supplied via the SME and with information specific to the MAC layer. There are no normative requirements on how any TSPEC is to be generated. However, in this subclause a description is given of how and where certain parameters can be chosen. The following parameters typically arise from the application: Nominal MSDU Size, Maximum MSDU Size, Minimum Service Interval, Maximum Service Interval, Inactivity Interval, Minimum Data Rate, Mean Data Rate, Burst Size, Peak Data Rate, and Delay Bound. The following parameters are generated locally within the MAC: Minimum PHY Rate and Surplus Bandwidth Allowance, although the Maximum Service Interval and Minimum Service Intervals can be generated within the MLME as well. This subclause describes how the parameters that are typically generated within the MAC can be derived.

Note that a TSPEC can also be generated autonomously by the MAC without any initiation by the SME. However, if a TSPEC is generated subsequently by the SME, the TSPEC generated autonomously by the MAC is overridden. If one or more TSPECs are initiated by the SME, the autonomous TSPEC, containing the same TSID is terminated.

Typically, TSPEC parameters not determined by the application are built upon the assumption that the following exist:

- A probability $p$ of not transmitting the frame (because it would have exceeded its delay bound)
- An MSDU length (which can be considered fixed for constant-bit-rate applications)
- Application throughput and delay requirements
- A channel model of error, in particular a channel error probability for the (fixed) frame length
- Possibly country-specific limits on TXOP limits

The minimum service interval, if determined within the MAC, can typically be given as the nominal MSDU size/mean data rate.
The maximum service interval, if determined within the MAC, can be calculated as the delay bound/number of retries possible. This number should be greater than the minimum SI, when that is specified. The number of retries can be chosen (as below) to meet a particular probability of dropping a packet because it exceeds its delay bound. Note that for multiple streams, this SI should be the aggregate of all SIs requested, because the STA is assigned the TXOPs, not any particular stream.

Typically, it can be assumed that the scheduler would attempt to schedule TXOPs distributed throughout a small multiple of beacon intervals (if not a single beacon interval). In addition, TXOP limits would typically be chosen to be as short as possible (within the constraints of the minimum PHY rate, acknowledgment policy, and so forth), consistent with the goal of maximizing throughput. In other words, because of overhead, not to mention the requirements for transmitting a single Poll frame, MPDU, and possibly ACK frame, the TXOPs need to be at least of a certain duration.

The channel model implies an error ratio and an assumption about dependency (joint probability distribution of channel errors sequentially, i.e., burst error probabilities).

For example, if the channel causes errors independently from frame to frame and the error probability is the same for all frames of the same length at all times, this channel would be said to be an independent, identically distributed error channel. With $p$ as the probability of dropping the frame, and $p_e$ as the probability of the frame not being transmitted successfully (i.e., either the data frame or the ACK frame associated with it is in error), let $N_p$ be the number of retries required to maintain the probability of dropping the frame to be $p$.

The probability of any given packet being dropped in such a channel after $N_p$ retries is given by

$$P_{drop} = (p_e)^{N_p}$$

For example, in such a channel, if $p_e = 0.1$ and $p_{drop} = 10^{-8}$, then up to seven retries within the delay bound are required, and the scheduler should ensure that sufficient cumulative TXOP allocations are made to accommodate retransmissions.

The Surplus Bandwidth Allowance parameter ensures the requesting STA is allocated a minimum amount of excess time by the scheduler to so that application dropped packet rates are bounded. For example, this parameter can be chosen to ensure that when there is a 10% packet error ratio (PER) for 1000-octet packets, there is a dropped PER (i.e., packets that fail to be received within the delay bound) of $10^{-8}$. This parameter can be chosen based on an initial assumption regarding channel/source characteristics and renegotiated by sending ADDTS Request frames if required, based on actual transmission behavior. To understand how this parameter can be specified, consider the case where there are only 100 PPDUs to be transmitted and delay is not an issue. The PER $p_e$ is 10%, with the errors happening independently from packet to packet. To accomplish this, the number of packets transmitted in each beacon interval must exceed the 100 PPDUs by $N_{excess}$ in order to avoid dropping packets with some fixed probability (denoted as $p_{drop}$).

For example, if $p_{drop} = 10^{-8}$, then the number of retries $N_{excess}$ must satisfy to send only 100 packets successfully (based on Bernoulli distributed error probabilities):

$$P_{drop} = \sum_{k = N_{excess}}^{N_{excess} + 100} \left( \binom{N_{excess} + 100}{k} p_e^k (1 - p_e)^{100 + N_{excess} - k} \right)$$

where $p_e = 0.1$. Solution of an equation such as this yields the total number of additional retries. This can be found, for this example, using the fact that
where \( I_{p_e}(a, b) \) is the Incomplete Beta function, and taking \( n \) sufficiently large (or invoking the law of large numbers). Solving this yields that, on the average, 38 additional MPDUs are required to keep the probability of dropping a packet to less than \( 10^{-8} \) to send only 100 packets. For this case, the

\[
\text{Surplus bandwidth allowance} = \frac{100 + N_{\text{excess}}}{100}, \quad \text{which for this example would be 1.38.}
\]

This might represent an upper bound for the excess bandwidth for many applications: it presumes that the observation interval is \( 100 + N_{\text{excess}} \) frames. When the observation interval (or delay bound) is longer than the time it takes to transmit 100 frames, then it can be shown that the excess bandwidth required decreases. For example, if it were desired to send 100 000 frames with 12 000 frames excess, then the probability of a dropped frame becomes \( 1.6 \times 10^{-15} \).

On the other hand, suppose that an infinitely long stream was to be transmitted without any constraints on delay. In such a case, with an infinite number of retries and with a 10% PER, 1.111 times the bandwidth required to send MPDUs without error is required (because the probability that \( n \) retries are required for any packet is given by \( 0.1^n \)).

In fact, assuming a finite delay bound, the above result (1.111= surplus bandwidth allowance) represents a lower bound on what the surplus bandwidth allowance would be.

Typically, then the excess bandwidth required would be between a “send only \( N + \) excess packets” scenario within a given delay and “send an infinite number of packets with an infinite number of retries with no delay” scenario.

A more exact calculation can be done via simulation as follows: Suppose there are \( N_{\text{allocated}} \) constant length PPDUs per beacon interval (these are actually transmitted on the air), and suppose there are \( N_{\text{payload}} \) constant length PPDUs to be transmitted. Suppose further that these transmitted and payload PPDUs arrive in a uniformly distributed manner in each beacon interval, then the delay incurred in waiting for a packet to be transmitted can be inferred from examining the transmit queue length and statistically can be inferred from examining how many retries within a certain period of time are required to keep the probability of a dropped packet below a certain amount. The number of retries (and consideration of IFS, polls, etc.) then determines the surplus bandwidth allowance.

In general, then the surplus bandwidth allowance can be given by \( \frac{N_{\text{allocated}}}{N_{\text{payload}}} \).

Note that for the case of a Block Ack, a similar calculation applies, although the calculations for the excess bandwidth need to take into account the probability of failing to receive a Block Ack, and so forth.

**N.3.3 Reference design for sample scheduler and admission control unit**

This subclause provides the guidelines for the design of a simple scheduler and admission control unit (the unit that administers admission policy in the HC’s SME) that meet the minimum performance requirements as specified in 9.19.4.3. The scheduler and admission control unit use the minimum set of mandatory TSPEC parameters as specified in 9.19.4.3.
N.3.3.1 Sample scheduler

This subclause includes the reference design for a sample scheduler. This scheduler uses the mandatory set of TSPEC parameters to generate a schedule: Mean Data Rate, Nominal MSDU Size, and Maximum Service Interval or Delay Bound. If both Maximum Service Interval and Delay Bound parameters are specified in the TSPEC, the scheduler uses the Maximum Service Interval parameter for the calculation of the schedule.

The schedule generated by the scheduler meets the normative behavior as specified in 9.19.4.3. The schedule for an admitted stream is calculated in two steps. The first step is the calculation of the scheduled SI. In the second step, the TXOP duration for a given SI is calculated for the stream.

The calculation of the scheduled service interval is done as follows: First, the scheduler calculates the minimum of all maximum SIs for all admitted streams. Let this minimum be \( m \). Second, the scheduler chooses a number lower than \( m \) that is a submultiple of the beacon interval. This value is the scheduled SI for all STAs with admitted streams. See Figure N-1.

For the calculation of the TXOP duration for an admitted stream, the scheduler uses the following parameters: Mean Data Rate and Nominal MSDU Size; and from the negotiated TSPEC, the Scheduled Service Interval calculated above, Physical Transmission Rate, Maximum Allowable Size of MSDU, and Overhead. The Physical Transmission Rate is the minimum PHY rate negotiated in the TSPEC. If the minimum PHY rate is not committed in the ADDTS Response frame, the scheduler can use the observed PHY rate as the Physical Transmission Rate. The Overhead includes IFSs, ACK frames and CF-Poll frames. For simplicity, details for the Overhead calculation are omitted in this description. The TXOP duration is calculated as follows: First, the scheduler calculates the number of MSDUs that can arrive at the Mean Data Rate during the SI:

\[
N_i = \left\lfloor \frac{SI \times \rho_i}{L_i} \right\rfloor
\]

where
- \( SI \) is the Scheduled Service Interval
- \( \rho \) is the Mean Data Rate
- \( L \) is the Nominal MSDU Size

Then the scheduler calculates the TXOP duration as the maximum of
- Time to transmit \( N_i \) frames at \( R_i \) and
- Time to transmit one maximum size MSDU at \( R_i \) (plus overhead):

\[
TXOP_i = \max \left( \frac{N_i \times L_i}{R_i} + O \left( \frac{M}{R_i} + O \right) \right)
\]

where
- \( R \) is the Physical Transmission Rate
is the maximum possible size of MSDU, i.e., 2304 octets

is the Overhead in time units

An example is shown in Figure N-1. Stream from STA \(i\) is admitted. The beacon interval is 100 ms and the maximum SI for the stream is 60 ms. The scheduler calculates a scheduled SI \((S_I)\) equal to 50 ms using the steps explained above is this annex.

The same process is repeated continuously while the maximum SI for the admitted stream is larger than the current SI. An example is shown in Figure N-2.

If a new stream is admitted with a maximum SI smaller than the current SI, the scheduler needs to change the current SI to a smaller number than the maximum SI of the newly admitted stream. Therefore, the TXOP duration for the current admitted streams needs also to be recalculated with the new SI.

If a stream is dropped, the scheduler might use the time available to resume contention. The scheduler might also choose to move the TXOPs for the STAs following the STA dropped to use the unused time. An example is shown in Figure N-3, when the stream for STA \(j\) is removed. However, this option might require the announcement of a new schedule to all STAs.

Different modifications can be implemented to improve the performance of the minimum scheduler. For example, a scheduler might generate different scheduled SIs \((S_I)\) for different STAs, and/or a scheduler might consider accommodating retransmissions while allocating TXOP durations.

### N.3.3.2 Admission control unit

This subclause describes a reference design for an admission control unit (ACU) that administers admission of TS. The ACU uses the same set of parameters that the scheduler uses in N.3.3.1.

When a new stream requests admission, the admission control process is done in three steps. First, the ACU calculates the number of MSDUs that arrive at the mean data rate during the scheduled SI. The scheduled SI \((S_I)\) is the one that the scheduler calculates for the stream as specified in N.3.3.1. For the calculation of the number of MSDUs, the ACU uses the equation for \(N_i\) shown in N.3.3.1. Second, the ACU calculates the TXOP duration that needs to be allocated for the stream. The ACU uses the equation for \(TXOP_i\) shown in N.3.3.1. Finally, the ACU determines that the stream can be admitted when the following inequality is satisfied:
\[
\frac{TXOP_{k+1}}{ST} + \sum_{i=1}^{k} \frac{TXOP_i}{ST} \leq \frac{T - T_{CP}}{T}
\]

where
- \( k \) is the number of existing streams
- \( k + 1 \) is used as index for the newly arriving stream
- \( T \) indicates the beacon interval
- \( T_{CP} \) is the time used for EDCA traffic

The ACU needs to ensure that it complies with the dot11CAPlimit, i.e., the scheduler does not allocate TXOPs that exceed dot11CAPlimit. The ACU might also consider additional time to allow for retransmissions.

The ACU ensures that all admitted streams have guaranteed access to the channel. Any modification can be implemented for the design of the ACU. For example, UP-based ACU is possible by examining the UP field in TSPEC to decide whether to admit, retain, or drop a stream. If the UP is not specified, a default value of 0 is used. If a higher UP stream needs to be serviced, an ACU might drop lower UP streams.
Annex O

(informative)

An example of encoding a TIM virtual bit map

O.1 Introduction

The purpose of this annex is to show an example of encoding a Partial Virtual Bit Map field of the TIM element of the MAC, as described in 8.4.2.7.

O.2 Examples

The following examples help clarify the use of TIM values, both with and without the Multiple BSSID capability.

The first example is one in which there are no group addressed MSDUs buffered in the AP but there is traffic for two STAs queued in the AP. STAs with AID 2 and AID 7 have data buffered in the AP. Figure O-1 shows the values of the Bit Map Control and Partial Virtual Bit Map fields that would be part of the TIM element for this example.

The next example is one in which group addressed MSDUs are buffered in the AP as well as traffic for STAs. The DTIM Count field in the TIM element equals 0. STAs with AID 2, AID 7, AID 22 and AID 24 have data buffered in the AP. Figure O-2 shows the values of the Bit Map Control and Partial Virtual Bit Map fields.

Another example is one in which group addressed MSDUs are buffered in the AP as well as traffic for STAs. The DTIM Count field in the TIM element equals 0. Only the node with AID 24 has data buffered in the AP. In this example, the Bit Map Offset is used to start the Partial Virtual Bit Map at the third byte. Figure O-3 shows the values of the Bit Map Control and Partial Virtual Bit Map fields.

The three examples listed above describe the construction of the TIM Virtual Bitmap when the Multiple-BSSID capability is not supported. The following three examples demonstrate how to construct the TIM Virtual Bitmap, when Multiple-BSSID is supported.
The first example with Multiple BSSID is one in which there are eight BSSIDs and the lowest possible AID that can be assigned to any STA in this example is 8. There are no group addressed frames buffered in the AP for any of the eight BSSIDs. However, STAs with AID 9 and AID 11 have an individually addressed frames buffered in the AP. Figure O-4 shows the values of the Bitmap Control and Partial Virtual Bitmap fields that would be part of the TIM element for this example when either Method A or Method B is used. It is noted that Method B reduces to Method A in this example.

In the next example, there are eight BSSIDs and the lowest possible AID that can be assigned to any STA in this example is 8. There are group addressed frames buffered at the AP for the transmitted BSSID, and the DTIM Count field in the TIM element of the transmitted BSSID is 0. The nontransmitted BSSID with BSSID Index 3 also has the DTIM Count field set to 0 and has buffered group addressed frames. All other nontransmitted BSSIDs have no buffered group addressed frames. In addition, STAs with AID 12, AID 17, AID 22 and AID 24 have data buffered at the AP. Figure O-5 shows the values of the Bitmap Control and
Partial Virtual Bitmap fields that would be part of the TIM element for this example when either Method A or Method B is used. It is noted that Method B reduces to Method A in this example.

In the third example, there are sixteen BSSIDs and the lowest possible AID that can be assigned to any STA is 16. There are no group addressed frames buffered at the AP for the transmitted BSSID, and the DTIM Count field in the TIM element of the transmitted BSSID is 0. The nontransmitted BSSID Index 3 also has the DTIM Count field set to 0 and has group addressed frames buffered at the AP. All other nontransmitted BSSIDs have no buffered group addressed frames. In addition, the STA with AID 39 has individually addressed frames buffered at the AP. Figure O-6 and Figure O-7 show the values of the Bitmap Control and Partial Virtual Bitmap fields that would be part of the TIM element for this example when Method A and Method B are used, respectively.
O.3 Sample C code

The following C source code illustrates how to construct the TIM Virtual Bit Map. Because this is an illustration, no efficiency or appropriateness for actual implementation is implied.

```c
#include <stdio.h>
#include <limits.h>

#define ADD_TIM_BIT     0
#define REMOVE_TIM_BIT  1
#define TIM_ELEMENT_ID  5
#define TIM_BASE_SIZE   3       /* size of TIM fixed fields */
#define AID_SIZE        2008    /* valid AIDs are numBssids thru 2007 */
#define VBM_SIZE        251     /* size of VBM array = 2008/8 = 251 */
#define MAX_BSSIDS      128     /* maximum possible number of BSSIDs per AP, is a power of 2 */

typedef unsigned char UINT8;
typedef unsigned short int UINT16;

struct _tim
{
    UINT8 Element_id;
    UINT8 IELength;
    UINT8 DtimCount;
    UINT8 DtimPeriod;

Annex P

(informative)

Integration function

P.1 Introduction

The purpose of this annex is to guide the implementor of a WLAN system that includes a portal that integrates the WLAN system with a wired LAN.

P.2 Ethernet V2.0/IEEE 802.3 LAN integration function

It is recommended that any WLAN system that logically incorporates a portal that integrates the WLAN system with an Ethernet V2.0/IEEE 802.3 LAN use the procedures defined in ISO/IEC Technical Report 11802-5:1997(E) (previously known as IEEE Std 802.1H-1997), with the two-entry selective translation table (STT) shown in Table P-1, to perform the integration service. Note that the majority of such IEEE 802.11 implementations currently use this STT, rather than the single-entry STT recommended in Annex A of IEEE Std 802.1H-1997 [B21].

</tbody>
</table>

P.3 Example

In order to illustrate the translations performed by the integration service using the encapsulation/decapsulation procedures defined in ISO/IEC Technical Report 11802-5:1997(E) with the IEEE 802.11 integration service STT, the following tables show how the octets in an IEEE 802.11 MSDU correspond to the octets in the Ethernet/IEEE 802.3 MSDU that represents the same LLC SDU on the integrated Ethernet/IEEE 802.3 LAN. Table P-2 shows the encapsulation example, and Table P-3 shows the decapsulation example.

Note that examples in both tables showing a Type/Length field value of 81-00 represents bridging between an Ethernet/IEEE 802.3 LAN and an IEEE 802.11 LAN, both of which are carrying VLAN-tagged MSDUs (User Priority=4, CFI=0, VLAN ID=1893).

<sup>a</sup>This format of IP packet over IEEE Std 802.3 is denigrated, and the change to the canonical Ethernet IP format is not considered harmful.

<sup>b</sup>The use of this nonstandard format happens to work with these rules, even though the FF-FF is not actually a valid LLC header value. (The broadcast LSAP is not valid as a source SAP in LLC. See IEEE Std 802.2.)

<sup>c</sup>The sequence of octets AA-AA-03-00-00-00-81-00-87-65 represents the SNAP-encoded VLAN header. The sequence of octets AA-AA-03-00-00-00-08-00 represents the IEEE 802.1H-translated Type/Length field, using the same translation as the untagged IP MSDU on the first line of Table P-2.

</tbody>
</table>
There are a number of differences between the IEEE 802.11 integration service and the service provided by an IEEE 802.1 bridge. In the IEEE 802.11 architecture, a portal provides the minimum connectivity between an IEEE 802.11 WLAN system and a non-IEEE-802.11 LAN. Requiring an IEEE 802.1D bridge in order to be compliant with IEEE Std 802.11 would unnecessarily render some implementations noncompliant.

The most important distinction is that a portal has only one “port” (in the sense of IEEE Std 802.1D, for example) through which it accesses the DS. This renders it unnecessary to update bridging tables inside a portal each time a STA changes its association status. In other words, the details of distributing MSDUs inside the IEEE 802.11 WLAN need not be exposed to the portal.

Another difference is that the DS is not an IEEE 802 LAN (although it carries IEEE 802 LLC SDUs). Requiring that the DS implements all behaviors of an IEEE 802 LAN places an undue burden on the architecture.

Finally, it is an explicit intent of this standard to permit transparent integration of an IEEE 802.11 WLAN into another non-IEEE-802.11 LAN, including passing bridge PDUs through a portal. While an implementer may wish to attach an IEEE 802.1D bridge to the portal (note that the non-IEEE-802.11 LAN interface on the bridge need not be any particular type of LAN), it is not an architectural requirement of this standard to do so.

---

*This format of IP packet does not survive the trip across the non-IEEE-802.3 LAN intact.*
Annex Q
(informative)

AP functional description

Q.1 Introduction

This informative annex seeks to clarify the AP functional description. At times there is some confusion surrounding the term AP and the relation of that term to the AP functions and common implementations of AP devices. The core IEEE 802.11 conceptual definitions that surround the AP (refer to Clause 4) are abstract (and can sometimes cause confusion), but Clause 4 definitions are crafted to be flexible and hence serve to allow the adaptation and extension of this standard in a wide variety of ways.

Q.2 Terminology

An enhanced description of these access entities begins with clarification of several terms.

This standard defines an entity called a STA. STAs can operate in different modes. The possible operational modes of a STA are

a) Infrastructure mobile STAs
b) Ad hoc mobile STAs
c) Access control mode STAs
d) Mesh STAs

The mobile STAs are the STA entities that are ordinarily moving around, but may also be in a fixed location. The mobile adjective prefix often helps in visualizing the type of STA under discussion.

Infrastructure mobile STAs operate in infrastructure BSS mode, i.e., they are the users of an AP. Devices that incorporate an infrastructure mobile STA are referred to in this annex by the term mobile unit (MU). An MU device may consist of just a mobile STA implementation, but also likely includes an SME and a client. The exact configuration of the MU is not relevant to the descriptions in this annex.

Ad hoc mobile STAs operate in IBSS mode. Ad hoc mobile STAs form autonomous networks that do not require an AP.

A STA can also form an integral part of an AP. To do so, the STA must operate in access control mode. This type of STA is called an access control mode STA (ACM_STA).

The primary function of an AP is to provide the MUs with access to the DS, as shown in the Unified Modeling Language (UML) use case diagram in Figure Q-1. Complete UML specifications can be found in Rumbaugh [B54]. The UML diagram shows a system boundary box containing a single use case (ellipse). Entities that are outside the system boundary box are shown as stick people. These external entities represent the actors (formal term), or users, of the system. Since the actors are outside the system boundary, their internal behavior is not described (i.e., it is out of scope for the current view). Instead, references to the external entities are limited to descriptions of their interactions with, and expectations of, the system, which is accomplished by describing the use cases and scenarios (i.e., functions) of the system and later (in Figure Q-4) a decomposition of the entities (objects and behaviors) within the system that provide that functionality. The use case diagram employs connecting lines to indicate relationships between the various...
artifacts present in the diagram. Relationship lines lacking arrows on both ends indicate that there is a bidirectional relationship between the artifacts.

The DS enables communication between MUs and the construction of collections of APs. To enable communication between MUs and a non-IEEE-802.11-LAN entity requires the presence of a (logical) portal from the DS to the non-IEEE-802.11 LAN.

Often the functions of an AP, which includes an ACM_STA, a DS, and a portal, are combined into a single device, referred to in this annex as an access unit (AU). While reference to that basic implementation is commonplace, it is helpful to discuss the abstract case: a WLAN system. The WLAN system includes the DS, AP, the AP’s STA, and portal entities. It is also the logical location of distribution and integration service functions of an ESS. An infrastructure WLAN system contains one or more APs and zero or more portals in addition to the DS.

The primary function of a WLAN system is to provide the MUs with access to the non-IEEE-802.11 LAN, as shown in Figure Q-2. A secondary function is to provide the MUs with access to each other.

The primary functions of the WLAN system can be further characterized as follows:

a) Provide non-IEEE-802.11-LAN access.
   1) Includes MU validation.
   2) Includes moving data between the MUs and the non-IEEE-802.11 LAN.
      i) Uses a special data movement function called filtering data.

b) Configure the system.
Those high-level use cases of the WLAN system are shown in the UML use case diagram in Figure Q-3. The UML diagram shows multiple use cases with two types of relationships between those use cases: include and generalization. The include relationship “includes” functionality in one use case that is described by another use case. The “Provide LAN Access” use case includes the functionality of the “Validate MU” use case. The generalization relationship indicates that one use case is a more general form of another use case. The relationship line with a hollow triangle at the end indicates that the “Move Data” use case is a more generalized form of the “Filter Data” use case. Or, equivalently, “Filter Data” is a more specialized form of “Move Data.” The constraint artifact (in the lower left corner of the diagram) requires the WLAN system and the MUs to be set to the same SSID.

![Figure Q-3—High-level UML use case diagram for the WLAN system](image)

The primary functions of the WLAN system, depicted in the UML object model diagram in Figure Q-4, are provided by the ACM_STA, AP, and DS entities, the latter via the DSSs. The portal is merely a conceptual link from the DS to the non-IEEE-802.11 LAN. The UML object model diagram shows a package containing a set of object classes. References to the actors (external entities) are limited to descriptions of their interactions with, and expectations of, the object classes, which is accomplished by describing the attributes and behaviors of the class entities. The object model diagram uses connecting lines to indicate interfaces (called associations in UML terminology) between the various artifacts present in the diagram. UML association lines lacking arrows on both ends indicate that there is a bidirectional interface between the artifacts. The UML association lines are annotated with multiplicity counts to indicate the how many entities may fill the position at that end of the association.
Figure Q-4 also shows the relationships between the WLAN system entities. There exists a bidirectional association between zero or more \([0..\ast]\) MUs and a single (given) ACM_STA. The solid diamond terminated line indicates that there is a composition relationship between the ACM_STA and the AP, i.e., the AP is composed of (or always has an) ACM_STA. Hence there is a one-to-one mapping between APs and ACM_STAs. This composition and one-to-one relationship can also be drawn as shown in Figure Q-5. These two forms are equivalent. There are one or more \([1..\ast]\) APs connected to a single DS. The DS in turn connects to zero or more \([0..\ast]\) portals. Each portal connects to a single non-IEEE-802.11 LAN.
The primary functions of an ACM_STA are as follows:

a) Instantiate the infrastructure BSS.

b) Move data between the MUs and the AP.

Instantiating the infrastructure BSS consists of advertising the BSS and defining timing for the entire BSS (i.e., infrastructure mode TSF). Advertising the BSS includes creating an infrastructure mode Beacon frame, transmitting that Beacon frame, and replying to MU probe requests with corresponding probe response transmissions. Beacon frames and probe responses provide a way for the MUs to find, join with the ACM_STA, and (subsequently) associate with the AP. This includes, for example, the AP providing channel, regulatory, and country information to the MUs.

Moving data between the MUs and the AP consists of translating between MSDUs and MPDUs, buffering data, and transmitting/receiving MPDUs via an IEEE 802.11 PHY.

The primary functions of an AP are as follows:

a) Provide DS access for the MUs.

1) Includes MU validation and extends (in some cases) to notifying the DS.

2) Includes moving data between the MUs and the DS.

   i) Uses a special data movement function called data filtering.

b) Configure the AP (both the AP itself and the included ACM_STA).

Those high-level use cases of the AP are shown in the UML use case diagram in Figure Q-6. The UML extend relationship “extends” a use case with optional functions provided by another use case that are applied only in some scenarios. In Figure Q-6, the “Notify the DS” use case extends the “Validate MU” use case in some scenarios.
The AP provides DS access for the MUs, including validating the MUs (e.g., via STA and/or client authentication) and providing access and admission control (e.g., via the association process). An AP is literally a point of access to the DS (and, by extension, to the non-IEEE-802.11 LAN beyond). Upon validating an MU, the AP updates the DS mapping of the MU to the AP. DS mapping updates can, for example, be based on association and reassociation requests (received from the ACM_STA) or aging of inactive links (based on session timers). An AP may also receive access control updates directly from other APs, via a protocol outside the scope of this standard, in the form of inter-AP notifications of MU association events and transitions. In this way, MU validation and subsequent changes in MU access control lead to adjustments in how data are allowed to move through the AP (i.e., between the MUs and the DS).

Providing DS access for the MUs also includes moving data between the MUs and the DS, which is accomplished by moving MSDUs between the ACM_STA and the DS (bidirectionally).

The moving data function includes “filtering data.” The filtering data function controls which MSDUs (if any) are moved between the DS and the MUs. For example, filtering of data to and from a particular MU is adjusted based on the various stages of validation of that MU.

The AP also provides a function for configuration. Configuring the AP includes configuring the AP itself as well as the included ACM_STA. For example, configuration may include setting the local values of the SSID, PHY channel, beacon interval, and so on.
Q.5 Primary DS functions

The primary functions of the DS (i.e., the DSSs) are as follows:
   a) Map MU to AP (for DS-to-MU traffic delivery).
   b) Move data.

The DS’s MU-to-AP map determines which AP is to be used for a given MU’s data delivery. This function includes mapping update adjustments, which are based on notification from the APs, of changes in MU access control.

Moving data consists of moving MSDUs among the APs (including returning MSDUs to the source AP for MU-to-MU communications) and between the APs and the portal(s).

Q.6 Primary portal function

The primary function of a portal is as follows:
   a) Move data with a special data movement function called data transformation.

Moving data consists of moving MSDUs between the DS and the external non-IEEE-802.11 LAN. Moving data through the portal transforms the MSDUs using the integration function. The integration function translates external non-IEEE-802.11-LAN MSDUs to and from IEEE 802.11 MSDUs using, for example, the procedures defined in Annex P.

Q.7 AU example

Now that the functions of a WLAN system have been described, here is the example of an AU implementation. Quite simply, an AU is an instantiation of a WLAN system as described in this annex.

Since transiting from a DS through a portal onto an integrated non-IEEE-802.11 LAN and then subsequently via another portal onto its DS is transparent, it is possible to define a DS in terms of not only the portals that are directly connected to a particular DS, but also in terms of all the integrated MAC endpoints. Therefore, a collection of AUs connected to an integrated non-IEEE-802.11 LAN can define a DS that consists of the union of all the DSs inside the AUs. The union of such a set of AUs would itself constitute a WLAN system.
Annex R
(informative)

DS SAP specification

R.1 Introduction

The purpose of this informative annex is to describe and clarify the DS SAP. The DS SAP is the interface between the DS SAP service users and the DS SAP service provider. The DS SAP service users are the connected APs, mesh gates, and portals. The DS SAP service provider is the DS. Figure R-1 shows the location of the DS SAP in the IEEE 802.11 architecture.

The DS SAP interface specification describes the primitives required to get MSDUs in and out of the DS and update the DS’s mapping of STAs to APs or to mesh gates. Describing the DS itself or the functions thereof is out of scope of this annex.

The DS SAP actions are as follows:
  a) Accept MSDUs from APs, mesh gates, and portals.
  b) Deliver MSDUs to APs, mesh gates, or portals.
  c) Accept STA-to-AP mapping updates from the APs.
  d) Accept STA-to-mesh gate mapping updates from the mesh gates.

When the DS delivers the MSDUs to an AP, the AP then determines when and how to deliver the MSDUs to the AP’s MAC (via the MAC SAP). When the DS delivers the MSDUs to a mesh gate, the mesh gate then determines when and how to deliver the MSDUs to the mesh gate's MAC (via the MAC SAP).
R.2 SAP primitives

R.2.1 General

The DS SAP service interface primitives are as follows:

a) DS-UNITDATA.request
b) DS-UNITDATA.indication
c) DS-STA-NOTIFY.request

R.2.2 MSDU transfer

R.2.2.1 General

The DS-UNITDATA primitives accept and deliver IEEE 802.11 MSDUs, including all the parameters and data as defined in 5.2.2.2. These tuples are called distribution system service data units (DSSDUs).

R.2.2.2 DS-UNITDATA.request

R.2.2.2.1 Function

This primitive requests distribution of a DSSDU across the DS.

R.2.2.2.2 Semantics of the service primitive

The primitive parameters are as follows:

\[
\text{DS-UNITDATA.request(}
\text{Dssdu,}
\text{SourceType}
\text{)}
\]

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Valid range</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dssdu</td>
<td>IEEE 802.11 MSDU</td>
<td>Any valid data unit according to 5.2.2.2, including data and all parameters</td>
<td>Specifies the DSSDU to be distributed via the DS.</td>
</tr>
<tr>
<td>SourceType</td>
<td>Enumeration</td>
<td>SRC_AP, SRC_MESH_GATE, SRC_PORTAL</td>
<td>Specifies the type of entity that is requesting distribution of a DSSDU.</td>
</tr>
</tbody>
</table>

R.2.2.2.3 When generated

This primitive is generated by an AP, mesh gate, or portal to submit a DSSDU to the DS for distribution.

R.2.2.2.4 Effect of receipt

This primitive initiates distribution of the DSSDU through the DS. An individually addressed DSSDU from an AP, mesh gate, or portal is distributed through the DS to the corresponding AP, mesh gate, or portal. A group addressed DSSDU from an AP is distributed to all APs, mesh gates, and portals, including the originating entity. A group addressed DSSDU from a portal is distributed to all APs, mesh gates, and portals, except the originating portal.
R.2.2.3 DS-UNITDATA.indication

R.2.2.3.1 Function

This primitive indicates delivery of a DSSDU from the DS to an AP, mesh gate, or portal.

R.2.2.3.2 Semantics of the service primitive

The primitive parameters are as follows:

```
DS-UNITDATA.indication(
    Dssdu
)
```

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Valid range</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dssdu</td>
<td>IEEE 802.11 MSDU</td>
<td>Any valid data unit according to 5.2.2.2, including data and all parameters</td>
<td>Specifies the DSSDU that is being delivered by the DS.</td>
</tr>
</tbody>
</table>

R.2.2.3.3 When generated

This primitive is generated by the DS to deliver a DSSDU to an AP, mesh gate, or portal.

R.2.2.3.4 Effect of receipt

This primitive delivers a DSSDU to an AP, mesh gate, or portal.

R.2.3 Mapping updates

R.2.3.1 General

The DS-STA-NOTIFY primitive is used to maintain the STA-to-AP and mesh STA-to-mesh gate mapping data of the DS.

R.2.3.2 DS-STA-NOTIFY.request

R.2.3.2.1 Function

This primitive requests an update to the DS’s STA-to-AP map or mesh STA-to-mesh gate map.

R.2.3.2.2 Semantics of the service primitive

The primitive parameters are as follows:

```
DS-STA-NOTIFY.request(
    STAAddress,
    UpdateType
)
```
R.2.3.2.3 When generated

This primitive is generated by an AP or mesh gate to update the DS’s STA-to-AP map or mesh STA-to-mesh gate map.

R.2.3.2.4 Effect of receipt

When generated by an AP, this primitive updates the DS’s STA-to-AP map, which controls to which AP the DS delivers DSSDUs that are destined for a given STA.

When generated by a mesh gate, this primitive updates the DS’s mesh STA-to-mesh gate map, which controls to which mesh gate the DS delivers DSSDUs that are destined for a given mesh STA. The mesh STA-to-mesh gate map can be incomplete.

There are many mechanisms to implement this mapping update for the cases of ADD and MOVE. One example mechanism, in the case where the DS is an IEEE 802 LAN, is to use an IEEE 802.2 XID null frame.

Annex S

(informative)

Additional HT information

S.1 Waveform generator tool

As an informative extension to this standard, the waveform generator tool has been written to model the PHY transmission process described in Clause 18, Clause 19, and Clause 20.

The waveform generator can be downloaded from the public IEEE 802.11 document website. The waveform generator code may be found in document 11-06/1715, and the waveform generator description may be found in document 11-06/1714.

The purpose of the tool is to promote common understanding of complex PHY algorithms, facilitate device interoperability by providing reference test vectors, and assist researchers in industry and academia to develop next generation wireless solutions.

The code is written in the MATLAB computing language and can be configured to generate test vectors for most PHY configurations, defined by this standard. Instructions on how to configure and run the Tool are specified in the documentation files that are supplied with the code. A command line interface and graphic user interface (GUI) exist to configure the tool. For consistency with this standard, the configuration interface is made very similar to the TXVECTOR parameters defined in 20.2.2.

The waveform generator tool produces test vectors for all transmitter blocks, defined in Figure 20-2 and Figure 20-3, generating reference samples in both frequency and time domains. Outputs of the tool are time domain samples for all transmitting chains.

S.2 A-MPDU deaggregation

This subclause contains a description of the deaggregation process. Other implementations are also possible.

The receiver checks the MPDU delimiter for validity based on the CRC. It can also check that the length indicated is within the value of the LENGTH parameter indicated in RXVECTOR.

If the MPDU delimiter is valid, the MPDU is extracted from the A-MPDU. The next MPDU delimiter is expected at the first multiple of 4 octets immediately after the current MPDU. This process is continued until the end of the PPDU is reached.

If the MPDU delimiter is not valid, the deaggregation process skips forward 4 octets and checks to see whether the new location contains a valid MPDU delimiter. It continues searching until either a valid delimiter is found or the end of the PSDU is reached based on the value of the LENGTH parameter indicated in the RXVECTOR.57

An A-MPDU parsing (deaggregation) algorithm is expressed (as a C programming language snippet) in Figure S-1.

57 This procedure occasionally wrongly interprets a random bit-pattern as a valid delimiter. When this happens, the MAC attempts to interpret a random MPDU. The MAC discards it with a high probability based on a bad MAC CRC check.
void Parse_A_MPDU (int length)
{
    int offset = 0; /* Octet offset from start of PSDU */
    while (offset+4 < length)
    {
        if (valid_MPDU_delimiter(offset) &&
            get_MPDU_length(offset) <= (length -(offset+4)))
        {
            /* Valid delimiter */
            /* Receive the MPDU */
            Receive_MPDU(offset+4, get_MPDU_length(offset));

            /* advance by MPDU length rounded up to a multiple of 4 */
            offset += 4 + 4*((get_MPDU_length(offset)+3)/4);
        }
        else /* Invalid delimiter */
        {
            /* Advance 4 octets and try again */
            offset += 4;
        }
    }
}

NOTE 1—This algorithm is not optimized for efficiency.

NOTE 2—The delimiter signature can be used to reduce the amount of computation required while scanning for a valid delimiter. In this case, the receiver tests each possible delimiter for a matching Delimiter Signature field. Only when a match is discovered does it then check the CRC.

Figure S-1—A-MPDU parsing
S.3 Example of an RD exchange sequence

Figure S-2 shows an example of the operation of the RD rules, defined in 9.25.

The following is a summary of Figure S-2:

a) STA A (acting as RD initiator) transmits a PPDU containing MPDUs addressed to STA B (acting as RD responder). The Ack Policy field of the QoS data MPDUs in this PPDU is set to Implicit Block Ack Request. One or more MPDUs within this PPDU include an HT Control field with the RDG/More PPDU subfield set to 1, indicating an RDG. The Duration/ID field of MPDUs within the PPDU contains the remaining duration of the TXOP, \( t \) µs.

b) STA B (the RD responder) responds with the transmission of a +HTC BlockAck frame in which the RDG/More PPDU subfield is set to 1, indicating that another PPDU will follow a SIFS or RIFS interval after the end of the PPDU containing the BlockAck MPDU.

c) STA B transmits a PPDU (the second PPDU of an RD response burst) to STA A, with the Ack Policy field of its QoS data MPDUs set to Implicit Block Ack Request and containing one or more +HTC MPDUs in which the RDG/More PPDU subfield is set to 0, indicating that this is the last PPDU in the response burst.

d) STA A (the RD initiator) regains control of the TXOP and transmits a BlockAck MPDU addressed to STA B to acknowledge the MPDUs transmitted by STA B in the RD response burst.

e) STA A (the RD initiator) transmits a PPDU containing MPDUs addressed to STA C (acting as RD responder). The Ack Policy field of the QoS data MPDUs in this PPDU is set to Implicit Block Ack. This PPDU includes one or more +HTC MPDUs in which the RDG/More PPDU subfield is set to 1, indicating an RDG. The Duration/ID field of MPDUs in the PPDU contains the remaining duration of the TXOP, \( t_0 \) µs.
f) STA C (the RD responder) transmits a PPDU to STA A, containing one or more +HTC MPDUs with the RDG/More PPDU subfield set to 0, indicating that this is the last PPDU in the response burst. This PPDU contains a BlockAck MPDU that is a response to the Implicit Block Ack request of the previous PPDU, plus QoS data MPDUs with the Ack Policy field set to Implicit Block Ack.

g) STA A (the RD initiator) regains control of the TXOP and transmits a BlockAck MPDU to STA C that acknowledges the MPDUs transmitted by STA C. This PPDU contains one or more +HTC MPDUs with the RDG/More PPDU subfield set to 1, indicating an RDG. The Duration/ID field of MPDUs in the PPDU contains the remaining duration of the TXOP, t1 μs.

h) STA C (the RD responder) transmits a PPDU to STA A, containing QoS data +HTC MPDUs with the Ack Policy field set to Implicit Block Ack Request and the RDG/More PPDU subfield set to 0. This is the only PPDU in the RD response burst.

i) STA A transmits a BlockAck MPDU to STA C that acknowledges the MPDUs transmitted by STA C in the RD response burst.

**S.4 Illustration of determination of NDP addresses**

Determination of NDP SA and DA are illustrated in Figure S-3 and Figure S-4.

S.5 20/40 MHz BSS establishment and maintenance

S.5.1 Signaling 20/40 MHz BSS capability and operation

A BSS that occupies 40 MHz of bandwidth and that is administered by an HT AP is called a 20/40 MHz BSS.

An HT AP that has dot11FortyMHzOperationImplemented equal to true sets the Supported Channel Width Set subfield of the HT Capabilities element to a nonzero value and may optionally operate a 20/40 MHz BSS. The Supported Channel Width Set subfield of the HT Capabilities element that is transmitted by the AP indicates the possible operating mode of the BSS and of the AP, but the value in this field is not an indication of the current operating channel width of either the AP or the BSS.

An HT AP signals the operating width of the BSS through the Secondary Channel offset field of the HT Operation element. A nonzero value in this field indicates that a secondary channel exists; in other words, the BSS is a 20/40 MHz BSS. A value of 0 in this field indicates that the BSS is operating as a 20 MHz BSS.

An HT AP that has dot11FortyMHzOperationActivated equal to true sets its STA Channel Width field of the HT Operation element to a nonzero value. This field signals the current operating mode of the AP, not the BSS. An HT AP may operate a 20/40 MHz BSS while it is operating as a 20 MHz device. Such a situation would support, for example, 40 MHz bandwidth DLS traffic among associated STAs, but only 20 MHz bandwidth traffic between STAs and the AP.

S.5.2 Establishing a 20/40 MHz BSS

Before starting a 20/40 MHz BSS, an 40-MHz-capable HT AP is required by the rules defined in 10.15.5 to examine the channels of the current regulatory domain to determine whether the operation of a 20/40 MHz BSS might unfairly interfere with the operation of existing 20 MHz BSSs. The AP (or some of its associated HT STAs) is required to scan all of the channels of the current regulatory domain in order to ascertain the operating channels of any existing 20 MHz BSSs and 20/40 MHz BSSs. This type of scanning is called OBSS scanning. The particulars of OBSS scanning are controlled by the following MIB attributes:

- dot11FortyMHzOptionImplemented
- dot112040BSSCoexistenceManagementSupported
- dot11FortyMHzIntolerant
- dot11BSSWidthTriggerScanInterval
- dot11BSSWidthChannelTransitionDelayFactor
- dot11OBSSScanPassiveDwell
- dot11OBSSScanActiveDwell

![Figure S-4—Determination of NDP source and destination for bidirectional NDP sequence](image)
Specific values for these MIB attributes are provided to set minimum scan times for passive scanning of each channel, and a separate minimum time is provided for active scanning of each channel. A total minimum amount of scanning per channel is required before a determination can be made to allow the operation of a 20/40 MHz BSS.

The rules that are applied when determining whether a 20/40 MHz BSS can be established are intended to avoid a full or partial overlap of the secondary channel of the 20/40 MHz BSS with an existing primary channel of either a 20 MHz BSS or a 20/40 MHz BSS. The lack of partially overlapping channels in the 5 GHz band allows these rules to be written as recommendations, while in the 2.4 GHz band, they are requirements.

An additional constraint on establishing a 20/40 MHz BSS includes the allowance for any IEEE 802.11 device to explicitly prohibit the operation of the 20/40 BSS mode due to other considerations. For example, if an IEEE 802.15.1 WPAN device is operating in the area, that device is likely to be unable to communicate successfully with a paired receiver if the number of available IEEE 802.15.1 WPAN channels falls below a given threshold. Operation of a 20/40 MHz BSS in the 2.4 GHz band can contribute to the reduction of the number of available IEEE 802.15.1 WPAN channels, possibly pushing the available channels below that threshold.

To promote sharing of the spectrum resource under such circumstances, it might be desirable to prohibit the operation of a 20/40 MHz BSS. As such, the 20/40 BSS coexistence mechanism allows a STA to transmit management frames containing a value of 1 for the Forty MHz Intolerant field. (The MIB attribute dot11FortyMHzIntolerant determines the setting of the value of the Forty MHz Intolerant field in transmitted frames, and the setting of the value of the MIB attribute is beyond the scope of this standard.) Receivers of such frames on any channel in the band are not allowed to establish a 20/40 MHz BSS anywhere in the band for a duration of dot11BSSWidthChannelTransitionDelayFactor × dot11BSSWidthTriggerScanInterval seconds. To effect this requirement, monitoring STAs and APs maintain a countdown timer to indicate that a prohibition is in force. The countdown timer is reloaded with the value dot11BSSWidthChannelTransitionDelayFactor × dot11BSSWidthTriggerScanInterval seconds each time that the STA or AP observes a management frame containing a value of 1 for the Forty MHz Intolerant field. STAs communicate changes in their countdown counter (i.e., transitions between a zero value and a nonzero value) to their associated AP through the 20 MHz BSS Width Request field of the 20/40 BSS Coexistence Management frame.

S.5.3 Monitoring channels for other BSS operation

Some of the STAs that are associated with a 20/40 MHz BSS are required to perform monitoring in order to ensure that the conditions which allowed the establishment of the 20/40 MHz BSS do not change to conditions that would disallow the existence of the 20/40 MHz BSS.

Monitoring STAs keep a local record of channels that are in use by other BSSs. STAs that receive Beacon frames determine the primary channel by examining the DSSS Parameter Set element. Secondary channel existence and channel information are determined by examining the Secondary Channel Offset field of the 20/40 BSS Coexistence element. Monitoring STAs also record receptions of frames that contain a value of 1 for the Forty MHz Intolerant field. Any changes to the local record that would create a prohibition against 20/40 MHz BSS operation are immediately reported to the associated AP through the transmission of a 20/40 BSS Coexistence Management frame (i.e., with the 20 MHz BSS Width Request field set to 1). The reception of a 20 MHz BSS Width Request field equal to 1 at the AP causes the AP to switch the BSS to 20 MHz operation immediately.
Any change of a channel in use that had not previously been in use is also reported immediately within a 20/40 BSS Coexistence Management frame. The AP examines the new in-use channel information to determine whether any changes in BSS width operation are required (i.e., to see if any changes have occurred that indicate an overlap of the secondary channel). If a change to 20 MHz BSS operation is required, the change occurs immediately.

Conditions that prevent the operation of a 20/40 MHz BSS might be transient. If the number of channels in use is reduced or all STA signaling 40 MHz intolerance leave the area, an AP might choose to revert to 20/40 MHz operation, if allowed to do so. However, the conditions that allow 20/40 MHz BSS operation have to persist for a period of $\text{dot11BSSWidthChannelTransitionDelayFactor} \times \text{dot11BSSWidthTrigger-ScanInterval}$ seconds before a STA can signal that the conditions have changed, and the same period of time has elapsed before an AP can resume 20/40 MHz BSS operation.

STAs that do not monitor channels through OBSS scanning and do not report any channel information or received Forty MHz Intolerant field information to their associated AP are listed here:

- non-HT STAs
- HT STAs that are exempt from scanning as specified in 10.15.6
- HT APs, once the 20/40 MHz BSS is established
- HT STAs that are associated with an AP whose BSS is operating on a channel that is not in the 2.4 GHz band
- HT STAs that are associated with an HT AP that is not 40-MHz-capable (as indicated by a value of 0 in the Supported Channel Width Set subfield of the HT Capabilities element)

All other HT STAs that are associated with a 40-MHz-capable HT AP whose BSS is operating on a channel in the 2.4 GHz band monitor channels through OBSS scanning and report any channel information or received Forty MHz Intolerant field information to their associated AP.

All MIB attributes that are employed by the 20/40 BSS Coexistence mechanism are maintained by the AP, which has the ability to provide updates to the MIB attribute values to the associated STA by transmitting an OBSS Scan Parameters element.
Annex T

(informative)

Location and Time Difference accuracy test

T.1 Location via Time Difference of arrival

The location of a device may be determined in multiple methods, including the following:

— Signal strength at different sensors
— Time of flight between the device and different sensors
— Time difference of arrival between the device and pairs of sensors

A typical implementation of the time difference of arrival method requires that the sensors are co-channel, have synchronized clocks, and receive the same transmission from the device. The sensor’s time of arrival measurements are shared, and the device location is determined via multilateration, i.e., each pair of sensor measurements provides a time difference of arrival measurement that represents a hyperbola in 2D space of most likely candidate locations, and the overlap of the multiple hyperbola from multiple pairs of sensors leads to the location estimate. The single time of departure is not relevant in this typical multilateration implementation as it is canceled out when time differences of arrival are computed.

When the sensors are on different channels, such as APs in a typical multi-channel deployment, the device transmits on each channel and thus with multiple times of departure. In this environment it is necessary for the device to advertise each time of departure so that it can be subtracted from the times of arrivals measured by sensors on different channels. Furthermore, the device’s clock frequency typically does not match the clock frequency of the synchronized sensors, and so the device should transmit on the same channel multiple widely spaced times in order for the sensors to estimate the device’s clock frequency relative to themselves and to be able to suitably scale the device's advertised times of departure.

An example transmission sequence comprises frames transmitted on channels 1, 6, 11, 1 at 2.4 GHz. From this, the device’s clock frequency can be determined relative to the synchronized APs on channel 1, and all APs on channels 1, 6, and 11 can measure a time of arrival. These four transmissions enable a single location calculation. The Time of Departure Accuracy test in T.2 is designed to measure errors within such a transmission sequence that would degrade a multi-channel time difference of arrival location scheme.

T.2 Time Difference of departure accuracy test

The Time Difference of Departure accuracy test is an informative description of how time difference of departure accuracy can be measured for any parameterizable PHY waveform. This accuracy test does not apply when the Time of Departure timestamps are exclusively used for timing measurement (see 10.23.5).

The Time Difference of Departure accuracy test is parameterized by the following test parameters:

— TIME_OF_DEPARTURE\(_{(j,i)}\), 1 ≤ \(j\) ≤ 500, 1 ≤ \(i\) ≤ \(I\) (scalar entries)
— MULTICHANNEL_SAMPLING_RATE (scalar)
— FIRST_TRANSITION_FIELD\(_{(j,i)}\), 1 ≤ \(j\) ≤ 500, 1 ≤ \(i\) ≤ \(I\) (waveform entries)
— SECOND_TRANSITION_FIELD\(_{(j,i)}\), 1 ≤ \(j\) ≤ 500, 1 ≤ \(i\) ≤ \(I\) (waveform entries)
— TRAINING_FIELD\(_{(j,i)}\), 1 ≤ \(j\) ≤ 500, 1 ≤ \(i\) ≤ \(I\) (waveform entries)
— TIME_OF_DEPARTURE_ACCURACY_TEST_THRESH (scalar)
TIME_OF_DEPARTURE(j,i) is exposed externally through the TOD Timestamp field in the Time of Departure subelement in Location Track Notification frames.

The Time Difference of Departure accuracy test is performed as follows or in an equivalent or more accurate manner.

The Time Difference of Departure accuracy test is performed by instrumentation capable of converting signals transmitted on one or more channels into a stream of complex samples at $f_s$ sample/s or more, with sufficient accuracy in terms of I/Q arm amplitude and phase balance, dc offsets, phase noise, etc, and at a fixed delay from the transmitter. The minimum sampling rate is MULTICHANNEL_SAMPLING_RATE sample/s respectively. A possible embodiment of such a setup is converting the signal to a low IF frequency with a cabled microwave synthesizer, sampling the signal with a digital oscilloscope and decomposing it digitally into quadrature components. The sampled signal is processed in a manner similar to an actual time of arrival processor, according to the following steps:

a) Repeat steps b) to j) indexed by $j = 1, \ldots, 500$

b) Repeat steps c) to i) indexed by $i = 1, \ldots, I$

c) Start of frame is detected.

d) Channel number, coarse and fine frequency offsets are estimated.

e) The packet is derotated according to estimated frequency offsets.

f) The transition from FIRST_TRANSITION_FIELD$(j,i)$ to SECOND_TRANSITION_FIELD$(j,i)$ is detected; and fine timing (with one sample resolution) is established.

g) The TRAINING_FIELD$(j,i)$ of the derotated signal is up-sampled to meet the TIME_OF_DEPARTURE_ACCURACY_TEST_THRESH requirement. For example, a TIME_OF_DEPARTURE_ACCURACY_TEST_THRESH of 1 ns requires up-sampling of at least 1 GHz.

h) The up-sampled signal is cross-correlated with a reference waveform of the TRAINING_FIELD$(j,i)$

i) The measured time of departure $x_{j,i}$ is determined from the time of the peak of the magnitude of the cross-correlation.

NOTE—The time of the peak of the magnitude of the cross-correlation is actually a time of arrival measurement that equals the time of departure up to a fixed delay. Since the fixed delay is removed within step j), the fixed need not be known or explicitly compensated for.

j) Having repeated steps c) to i) $I$ times, the $(j,i)$th time of departure error $e_{j,i}$ is calculated as TIME_OF_DEPARTURE$(j,i)$ minus the synchronized time of departure. Defining $x_j = [x_{j,1}, \ldots, x_{j,I}]^T$ as the $I$ measured times of departure, $y = [\text{TIme\_Of\_Departure}(j,1), \ldots, \text{TIme\_Of\_Departure}(j,I)]^T$, $e_j = [e_{j,1}, e_{j,I}]^T$ are the $I$ time of departure errors and $X_j = [1_{I \times 1}, x_j]$, where $1_{I \times 1}$ is an $I \times 1$ matrix of ones, then the relative clock intercept, $rc_{ij}$, and slope, $rc_{sj}$, between device and instrumentation are determined as the linear least squares line of best fit: i.e., $[rc_{ij}, rc_{sj}]^T = (X_j^T X_j)^{-1} X_j^T y_j$. With these definitions and calculations, the synchronized time of departure $s_j = [s_{j,1}, \ldots, s_{j,I}]^T$ equals $rc_{sj} \times x_j + rc_{ij} \times 1_{I \times 1}$, and so the $I$ time of departure errors equal $e_j = y_j - s_j$

k) Having repeated steps b) to j) 500 times, there are $500 \times I$ values of the time of departure errors $e = [e_{1,1}, e_{500,I}]$

l) The Time of Departure accuracy test is passed if

1) The RMS value of $e$ is less than $aT_xP_{mdT_x}StartRMS$, and

2) $aT_xP_{mdT_x}StartRMS$ is less than TIME_OF_DEPARTURE_ACCURACY_TEST_THRESH, where the units of $e$, $aT_xP_{mdT_x}StartRMS$, and TIME_OF_DEPARTURE_ACCURACY_TEST_THRESH are properly accounted for.

NOTE 1—One possible implementation of a time of departure measurement system is a free-running oscillator clocking (a) the digital-to-analog converter(s) used to transmit the packet, (b) a 32-bit continuously counting counter and (c) a
hardware finite state machine such that PMD_TXSTART.request causes a transition within the finite state machine that in turn causes frame transmission at the DACs a fixed number of cycles later; where the time of departure is recorded as the value of the counter at that transition minus aTxPmdTxStartRFDelay (using TIME_OF_DEPARTURE_ClockRate), where aTxPmdTxStartRFDelay can vary by channel. In this implementation, the principal source of time of departure error is short term oscillator imperfection (e.g., phase noise) and RF group delay variation across channels uncompensated by aTxPmdTxStartRFDelay.

NOTE 2—1 ns of time of departure error corresponds to approximately 0.3 m of distance error, so high location accuracy depends upon a tight time of departure standard deviation.
Annex U

(informative)

Example use of the Destination URI for Event and Diagnostic Reports

U.1 Destination URI payload

An example of the payload used to transmit Event and Diagnostic reports shown in Table U-1. The protocol used to transport the Destination URI payload is beyond the scope of this standard. An example use of the Destination URI is given in U.2.

<table>
<thead>
<tr>
<th>Size (octets)</th>
<th>Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>6</td>
<td>BSSID</td>
</tr>
<tr>
<td>6</td>
<td>Reporting STA Address</td>
</tr>
<tr>
<td>variable</td>
<td>Event or Diagnostic Report frame contents</td>
</tr>
</tbody>
</table>

U.2 Use of HTTP (or HTTPS) for Destination URI of Event and Diagnostic Reports

Under certain conditions, a non-AP STA may need to send Event and Diagnostic reports to an AP using the Destination URI advertised by the AP in the request frame. A suitable higher layer protocol that could be used to transport the Event or Diagnostic report is HTTP or HTTPS.

For example, consider the following:

1) IT is investigating a WLAN coverage problem and uses a non-AP STA with a WLAN and Ethernet adapters to collect some additional information.
2) The non-AP STA with MAC 00:ff:fd:00:00:01 has received a Diagnostic Report request from AP 00:ff:fe:00:00:10 and is in fringe coverage. The non-AP STA has an Ethernet adapter that is connected.
4) The non-AP STA loses WLAN connectivity while trying to transmit a Diagnostic Report frame to the AP and the non-AP STA’s SME determines that it can use the Alternate Destination URI to send the Diagnostic Report frame using the Ethernet link.
5) The non-AP STA POSTs the Diagnostic Report as follows:
   POST /wnm/msg/00-ff-fd-00-00-01/msg1 HTTP/1.1
   Host: http://www.myserver.mycompany.com
   Content-Type: application/octet-stream
   Content-Encoding-Type: base64
   Content-Length: ?? (length of data as specified in Figure 8-470 in 8.5.14.5)
<encoded data = 00 ff fe 00 00 10 00 ff fd 00 00 01 …>

In the HTTPS case, the non-AP STA would need to be provisioned with credentials to establish the TLS connection prior to posting the message over HTTP. The HTTP post would work as described previously.
Annex V

(informative)

Interworking with external networks

V.1 General

The purpose of this informative annex is to describe and clarify the support for interworking with external networks including the support for network discovery and selection, QoS mapping, SSPN interface, and emergency services and to provide some background information and recommended practices.

V.2 Network discovery and selection

V.2.1 General

Interworking service provides features to support the network discovery and selection process a STA uses to choose the network with which to associate. GAS provides a non-AP STA access to an advertisement server (e.g., an access network server or an IEEE 802.21 information server), which can provide a rich set of information to aid the network discovery and selection process. In addition, interworking service provides lightweight features that also facilitate this process. The following subclauses describe several use cases illustrating how these features can be used to aid in network discovery and selection:

— **Airport**: A traveling businesswoman needs to connect via an airport hotspot to her enterprise network to download email and information from the customer database.
— **Shopping**: A shopper visits a shopping mall and wants to use a smartphone to discover items on sale.
— **Sales meeting**: A salesman visiting a customer accesses his guest network.
— **Museum**: A visitor to a museum uses a smartphone to obtain virtual docent service.
— **Emergency call**: A traveler needs to make an emergency call while in another country.
— **Emergency alert**: A traveler, having enabled the display of emergency alerts, arrives at a new destination.

V.2.2 Airport

A traveling businesswoman arrives for the first time at an airport having a WLAN. This user wants to download email onto her laptop utilizing the airport’s hotspot, a chargeable network. Once associated, the woman needs to connect via VPN connection back to her company’s servers to access email and information from the customer database. This is performed as follows:

a) The laptop’s non-AP STA performs an active scan by transmitting a Probe Request frame containing the wildcard SSID and an Interworking element with Access Network Type subfield set to “Chargeable Public Network.” In response, it receives Probe Response frames from several of the airport’s APs, in the immediate neighborhood, for the SSID “Narita Hotspot.”

b) The Probe Response received by the laptop indicated the following capabilities:
   1) Extended Capabilities element indicates: AP provides interworking service.
2) Interworking element indicates: venue group = 1 (Assembly) and venue type = 3 (passenger terminal), Internet = 1 (Internet access available), ASRA = 1 (there is an additional step required for network access).

3) Advertisement Protocol element including the Advertisement Protocol ID set to MIH Information Service.

4) Roaming Consortium element present containing an OI for “Hotspot Roaming International.”

5) There is no RSNE present in the received beacon frame.

c) Since the laptop’s SME does not recognize the Roaming Consortium OI, it invokes the GAS protocol to query the network’s IEEE 802.21 IS. The IEEE 802.21 IS’s response indicates the roaming partners for “Narita Hotspot” and the laptop have security credentials for one of them.

d) Since the AP indicated ASRA = 1, the SME again invokes the GAS protocol to retrieve the Network Authentication Type ANQP-element. The response indicates that https redirection is in use and provides the Redirect URL of hotspot.narita.co.jp. Note that this is helpful since some networks use conditional redirection—that is, access to a walled garden is provided for free, but a subscription fee is required to access the Internet.

e) Since the laptop’s SME now knows it should be able to successfully authenticate with the network, the STA associates to the AP.

f) The following operations are then carried out by higher layers operating within the laptop:

1) The laptop’s SME autonomously launches an http client and provides to it the URL of hotspot.narita.co.jp, which provides the proper security credentials to the network and thereby successfully authenticates it to the network.

2) The VPN client is autonomously launched and a secure session to the user’s corporate network is established. Then the user launches the email application to download email and other required information.

V.2.3 Shopping

A shopper visits a shopping mall and wants to use a smartphone to discover items on sale. In this mall, the mall’s IT department is providing WLAN facilities for all the stores in the mall; therefore, there is only one SSID for shoppers (i.e., there is not a different SSID for each store in the mall). The user arrives at the mall and taps an icon on the screen to put the smartphone in “shopping mode.” The smartphone’s shopping application causes the non-AP STA to carry out the following steps:

a) The smartphone’s non-AP STA performs an active scan by transmitting a Probe Request frame containing the wildcard SSID and an Interworking element with Access Network Type subfield set to “Free Public Network.” In response, it receives Probe Response frames from several of the mall’s APs, but only one SSID is provided, which is “Silicon Valley Mall.” The mall’s APs did not transmit Probe Responses for the SSIDs “Engineering,” “ Deliveries,” and “Janitorial” since their access network type is “Private network.”

b) The Probe Response received by the smartphone indicated the following capabilities:

1) Extended Capabilities element indicates: AP provides interworking service.

2) Interworking element indicates: venue group = 6 (mercantile) and venue type = 4 (shopping mall), Internet = 0 (unspecified).

3) RSNE indicates: IEEE 802.1X authentication.

c) Since the AP indicated Interworking service is available, the smartphone’s non-AP STA uses the MLME-GAS.request primitive to invoke GAS to request the Capability List ANQP-element (see 8.4.4.3). In the Capability List ANQP-element, the AP has indicated support for Venue Name and Domain Name. Subsequent to receipt of the Capability List ANQP-element, the non-AP STA invokes the MLME-GAS.request primitive to retrieve the other two lists.
d) Next, the non-AP STA’s Supplicant searches the received Domain Name list to determine whether it has any stored credentials for these domains. If so,
   1) The smartphone autonomously associates to the “Silicon Valley Mall Shopping” SSID and displays the following information:
      i) Venue Name: Silicon Valley Mall, 1234 Main Street, Rownhams, CA 98765-1234
      ii) SSID: Silicon Valley Mall
      iii) Venue type: Shopping Mall
   2) The Supplicant autonomously provides the security credentials for the selected domain.

e) Higher layer protocols then download discount coupons being offered for items on sale.

V.2.4 Sales meeting

A salesman travels across town to a meeting at ACME Manufacturing. While there, this user needs to send email to get a document from engineering. On his laptop, he requests the WLAN via the laptop’s UI to search for guest networks. The laptop performs the following steps:

a) The laptop’s non-AP STA performs an active scan by transmitting a Probe Request frame containing the wildcard SSID and an Interworking element with Access Network Type subfield set to “Private Network with Guest Access.” In response, it receives Probe Response frames from several of ACME Manufacturing’s APs, but only one SSID is provided, which is “Guest.” ACME Manufacturing’s APs did not transmit Probe Responses for the SSIDs “Engineering” and “Finance” since their access network type is “Private network.”

b) The Probe Response received by the laptop indicated the following capabilities:
   1) Extended Capabilities element indicates: AP provides interworking service.
   2) Interworking element indicates: Internet is available, venue group = 2 (Business) and venue type = 8 (Research and Development Facility).
   3) RSNE indicates: IEEE 802.1X authentication with CCMP pairwise and group cipher suites.

c) Since the AP indicated interworking service is available, the laptop’s non-AP STA uses the MLME-GAS.request primitive to invoke GAS to request the Capability List ANQP-element (see 8.4.4.3). In the Capability List ANQP-element, the AP has indicated support for Venue Name. Upon receipt of the Capability List ANQP-element, the non-AP STA again invokes the MLME-GAS.request primitive to retrieve the Venue Name.

d) The laptop’s UI displays the following information and automatically associates to the network:
   1) SSID: Guest (Type: Private network with Guest access)
   2) Venue Name: ACME Manufacturing, 1234 Main Street, Rownhams, CA 98765-1234
   3) Venue type: Research and Development Facility
   4) Internet is available

e) Upon prompt, the user enters the username and password supplied by his point of contact from ACME Manufacturing and is then able to send and receive email.

V.2.5 Museum

A visitor enters a museum that is advertising virtual docent service (audio tracks describing each of the major exhibits). The visitor taps an icon on a smartphone and requests it to search for free networks. The smartphone then carries out the following:

a) The smartphone’s non-AP STA performs an active scan by transmitting a Probe Request frame containing the wildcard SSID and an Interworking element with Access Network Type subfield set to “Free Public Network.” In response, it receives Probe Response frames from several of the museum’s APs, but only one SSID is provided, which is “Visitors.” The museum’s APs did not
transmit Probe Responses for the SSID “Maintenance” since its access network type is “Private network.”

b) The Probe Response received by the smartphone indicated the following capabilities:
   1) Extended Capabilities element indicates: AP provides interworking service.
   2) Interworking element indicates: venue group = 1 (assembly), venue type = 9 (museum), and ASRA = 0 (no additional steps are required for access).

c) Since the AP indicated interworking service is available, the smartphone’s non-AP STA uses the MLME-GAS.request primitive to invoke GAS to request the Capability List ANQP-element (see 8.4.4.3). In the Capability List ANQP-element, the AP has indicated support for Venue Name. Upon receipt of the Capability List ANQP-element, the non-AP STA again invokes the MLME-GAS.request primitive to retrieve the Venue Name.

d) The smartphone’s UI displays the following information, asking the user whether they wish to connect to the network:
   1) Venue Name: Museum of Modern Art (MOMA)
   2) SSID: Visitors
   3) Venue type: Museum
   4) No authentication required

e) The user taps the “Connect” icon on the smartphone’s display. Note that the smartphone’s non-AP STA knows that the network uses open system authentication since there is no RSNE present in the beacon and ASRA = 0.

V.2.6 Emergency call

A traveler needs to make an emergency call while in another country. The traveler may not be aware of the emergency call numbers that are used in that country. Being in this new location for the first time, the traveler is not aware of which local access points provide access for emergency calling. (Note that emergency calling requires higher layer application(s) that are outside the scope of this standard.) This is performed as follows:

a) The traveler’s non-AP STA performs an active scan by transmitting a Probe Request frame containing the wildcard SSID and an Interworking element. (If the non-AP STA is already associated with an AP that has indicated support for emergency service in its beacon, the probe request would not be necessary.)

b) In response, it receives Probe Response frames from one or more APs indicating support for emergency service in the Access Network Options field of the Interworking element.
   1) Extended Capabilities element indicates: AP provides interworking service.
   2) Emergency services reachability is indicated by the ESR and UESA fields in the Access Network Options field in the Interworking element.
   3) A dedicated emergency services network is indicated by the Access Network Type field in the Interworking element.

c) The traveler’s non-AP STA then requests the Emergency Call Number ANQP-element with a GAS Initial Request frame.

d) The GAS Initial Response frame from the AP provides the Emergency Call Number, for example the sequence of digits “911” or an emergency service URN label, URI pair “urn:service:sos.fire, tel:112;sip:+15555551002@fire.com” [B41].

e) This information is passed to the higher layer application in the traveler’s non-AP STA.

f) The traveler’s non-AP STA then associates with the AP.

g) The traveler’s non-AP STA then places the emergency call, with an expedited bandwidth request (EBR) in an ADDTS frame to provide priority to the emergency call.
V.2.7 Emergency alert

A traveler has enabled the display of emergency alerts on a wireless device (non-AP STA) by appropriately setting the higher layer emergency alert application on the device. The traveler arrives at a new destination and turns on the device. The device, when switched on, will perform a search and then associate with an AP to which the traveler has a subscription or associate with an open AP (if the traveler has enabled the device to do that). During the steps leading up to association, the device, when it becomes aware of an emergency alert, will obtain and display it. The emergency alert will likely be obtained from the AP that has the service to which the traveler has subscribed, but the device may also obtain the emergency alert from other APs, if an AP to which the traveler has a subscription is not available. This is performed as follows:

a) The traveler’s non-AP STA performs an active scan by transmitting a Probe Request frame containing the wildcard SSID. If it is associated with an AP, it checks the beacon.

b) In response, it receives Probe Response frames from one or more APs, which it checks (or, alternately, checks the beacon) for the subscription and also whether the Emergency Alert element indicates that there are emergency alert message(s).

c) If there are one or more emergency alert messages to be downloaded, the Emergency Alert Identifier element provides an Alert Identifier Hash value.

d) The device uses the hash of each of the available emergency message(s) to determine whether that message has already been received or whether it is a new message that must be downloaded.

e) If there are one or more emergency alert messages to be downloaded, the device forms the EAS Message URI by concatenating the Emergency Alert Server URI with the hexadecimal numerals of the Alert Identifier Hash, using the specified method.

f) Should the device be unassociated with an AP when it determines that a new emergency alert is available, it retrieves the EAS message using either GAS procedures with Advertisement Protocol ID field set to the value for EAS. If the device is associated with the AP, it retrieves the EAS message using either GAS procedures with Advertisement Protocol ID field set to the value for EAS or, for example, using HTTP.

V.3 QoS mapping guidelines for interworking with external networks

V.3.1 General

The EDCA and HCCA mechanism defined in 9.19 provide QoS control at the MAC layer. However, the QoS control parameters used by the EDCA and HCCA cannot match directly with other QoS control parameters of the interworked external networks, e.g., SSPN. For example, the SSPN could have different metrics for defining the QoS levels. Destination Network 1 (DN1) and DN2 can use DSCP values differently, in which case, STA1 and STA2 would require different QoS mapping information. Therefore, mapping from these external QoS control parameters to the QoS parameters of this standard is necessary.

The QoS parameters mapping can be used for both uplink and downlink data transmission:

— For uplink: at the non-AP STA, external QoS parameters are mapped to IEEE 802.11 QoS parameters, e.g., DSCP to IEEE 802.11 User Priority and in turn to EDCA ACs. This mapping helps the non-AP STA to construct correct QoS requests to the AP, e.g., ADDTS Request and to transmit frames at the correct priority.

— For downlink: at the AP, DSCP values are mapped to EDCA UPs. Optionally, the non-AP STA can use TSPEC and TCLAS elements in an ADDTS Request frame to setup a traffic stream in the BSS. In this method, the User Priority is specified in the TCLAS element. The policy used by the AP to choose a specific method to map frames to user priorities is outside the scope of this standard.
Different external networks can use different DSCP sets for the same services as described in V.3.3. For example, a 3GPP network can use different code points from that of an enterprise network. The QoS Map distribution mechanism defined in 10.24.9 provides means to communicate to the STA’s mapping information from the network.

**V.3.2 Determination of the mapping for a STA**

The QoS mapping to be applied depends upon the network the non-AP STA is accessing. In an interworking IEEE 802.11 infrastructure setting, the same physical AP can serve non-AP STAs from different SSPNs on different BSSIDs. As such, these STAs are separated into different BSSs. Figure V-1 presents an example of the scenario using authentication, authorization, and accounting (AAA). In Figure V-1, AAA Server 1 controls access to DN-1 and AAA Server 2 controls access to DN-2.

![Figure V-1—Interworking IEEE 802.11 infrastructure supporting multiple SSPNs](image)

**V.3.3 Example of QoS mapping from different networks**

IEEE 802.1d UPs map to EDCA ACs, as described in Table 9-1. The use of DSCP sets differs from network to network. Table V-1 shows examples of DSCP mappings.

NOTE—The mapping of the DSCP to 3GPP Traffic Class is available in GSMA, IR.34 v4.6 [B16] (similar to that of GSMA IREG34). See TR 21.905 [B2] for definition of general packet radio service (GPRS) roaming exchange. Table V-1 is extended to cover the EDCA ACs mapping. This mapping can also apply to other networks that adopt the 3GPP QoS definitions, e.g., 3GPP2.

Table V-2 shows an example mapping based on application classes defined in IETF RFC 4594. Mapping between DSCP and UP can be done using Exception fields or by range. The use of Exception fields will map a DSCP to a UP according to Table V-2. Mapping by range will require the setting of DSCP ranges as shown in Table V-3.
**Table V-1—Mapping table of DSCP to 3GPP QoS information and EDCA ACs**

V.4 Interworking and SSPN interface support

#### V.4.1 General

The interworking service architecture defines the scope of the SSPN interface. This interface is provided by the IEEE 802.11 MAC to support the interworking service. In an interworking scenario, the IEEE 802.11 infrastructure is operating in infrastructure mode.

Figure V-2 shows an example implementation of the control aspect of the Interworking Interface. As shown in the figure, the Interworking Interface consists of two parts: the generic SSPN Interface between the AP and the AAA Client; and the AAA Interface between the AAA Client and the corresponding AAA Server in the SSPN. Depending on the implementation the AAA Client can be collocated with the AP or stand alone serving as a proxy or translation agent between the SSPN Interface and AAA Interface. The AAA Interface serves as a transparent carrier of the SSPN interface.

The possible interactions over the SSPN interface are defined in 10.24.5. The information transferred over the SSPN Interface is defined in V.4.2. This interface results in parameters being set in the dot11InterworkingTable MIB. The AP’s SME thereafter uses these parameters to permit or deny, as appropriate, services to non-AP STAs.
V.4.2 SSPN interface parameters

The parameters for each associated non-AP STA defined in this clause cross the SSPN Interface, i.e., between AP and AAA Client as shown in Table V-4.

Table V-4—SSPN Interface information or permission parameters

Figure V-2—Basic architecture of the interworking service
The SSPN Interface parameters are stored in the AP with corresponding MIB attributes as defined in Annex C, and are used by the Interworking Service Management function in the SME. The MIB variables themselves, which are used by the APs SME, are read only.

**V.4.2.1 Non-AP STA MAC**

This is the MAC address of the non-AP STA accessing the interworking service through the AP. It can be requested by the external network, e.g., a 3GPP network, for fraud prevention. The non-AP STA MAC address is normally available through MLME-SAP, e.g., MLME-ASSOCIATE.indication, and should be forwarded by the AS to the AAA Server entity in the SSPN through the AAA Interface.

The AP stores the non-AP STA MAC address in the corresponding dot11NonAPStationMacAddress element of its MIB.

**V.4.2.2 Non-AP STA user ID**

This parameter contains the subscriber information of the non-AP STA for the interworking service. It is provided by the non-AP STA through the RSNA establishment process to the AAA Server; in turn, the AAA Server provides it back to the AP via the SSPN interface. It is in the form of a NAI, i.e., it contains both the user’s identity and its SSP information.

NOTE—The reason the AAA Server provides the user identity back to the AP is that some EAP methods use encrypted tunnels to maintain confidentiality of the user and thus the AP might not otherwise be able to learn the user’s identity.

The AP stores the associated non-AP STA User ID in the corresponding dot11NonAPStationUserIdentity element of its MIB.

**V.4.2.3 Non-AP STA interworking capability**

This parameter is derived from the non-AP STA’s Extended Capabilities element, which is included in (Re)Association Request frames. The AP SME obtains this information from the MLME-SAP, e.g., MLME-ASSOCIATE.indication. This information needs to be passed over the SSPN interface since the service authorization decisions can depend on the non-AP STA capabilities.

The AP stores the associated non-AP STA Interworking Capability in the corresponding dot11NonAPStationInterworkingCapability element of its MIB.

**V.4.2.4 Link layer encryption method**

This parameter indicates the link layer encryption method selected during the RSNA establishment process for protecting the unicast communication between the non-AP STA and the AP. The cipher suite format of this element is drawn from the RSNE defined in 8.4.2.27. The AP obtains this information about the STA via the MLME SAP.

In the interworking service, the SSPN also participates in the selection of the cipher suite selection, as described in 10.24.5. Therefore, the link layer encryption method selected will meet or exceed the security requirement of the SSPN.

NOTE—In interworking, the SSPN can require visibility and configurability of the STA access.

With this information available to the SSPN, the operator would be able to have better control, e.g., barring access to IEEE 802.11 networks if null encryption is used. This is also related to the operator network’s configuration, e.g., if preauthentication should be supported.

The AP stores the information in the corresponding dot11NonAPStationCipherSuite element of its MIB.
V.4.2.5 Authorized priority

This parameter is used for admission control and user-priority policing at the AP. It is based on the Infrastructure Authorization Information delivered from the SSPN during the AAA procedure. The Authorized Priority specifies the authorized User Priorities that the non-AP STA is allowed to use during the Interworking access. It also specifies whether the non-AP STA can use HCCA.

For EDCA operation, the AP stores the information in its corresponding dot11NonAPStationAuthAccessCategories element of its MIB after mapping the priority according to Table 9-1. For HCCA operation, the AP stores the information in dot11NonAPStationAuthHCCAHEMM.

V.4.2.6 Authorized maximum rate

This parameter is used for admission control decisions or policing actions at the AP. It is based on the Infrastructure Authorization Information delivered from the SSPN during the AAA procedure. For EDCA operation, this element contains a list of four MaxRate subelements indicating the maximum rate allowed for the access categories. For HCCA operation, there is one MaxRate subelement. Each of the MaxRate is an unsigned integer and in the unit of kilobits per second. An additional subelement provides the maximum rate at which a non-AP STA can source group addressed frames.

The AP stores the information in the corresponding dot11NonAPStationAuthMaxVoiceRate, dot11NonAPStationAuthMaxVideoRate, dot11NonAPStationAuthMaxBestEffortRate, dot11NonAPStationAuthMaxBackgroundRate, dot11NonAPStationAuthMaxHCCAHEMMRate and dot11NonAPStationAuthMaxSourceMulticastRate elements of its MIB.

V.4.2.7 Authorized service access type

This per-non-AP STA parameter indicates the access type allowed for the non-AP STA based on the SSPN decision. The AP will use this information for authorization requests from the STA, e.g., allow or disallow direct link operation and group addressed services. The element uses TruthValues to indicate the service type authorized. The following MIB variables are used:

- dot11NonAPStationAuthDls is to authorize a non-AP STA to use DLS
- dot11NonAPStationAuthSinkMulticast is to authorize a non-AP STA to request group addressed stream(s) from the network
- dot11NonAPStationAuthMaxSourceMulticastRate is to authorize a non-AP STA to source group addressed stream(s) to towards the network

V.4.2.8 Authorized delay

This parameter is used for admission control decisions at the AP. It is based on the Infrastructure Authorization Information delivered from the SSPN during the AAA procedure. This element is only used for HCCA operation, and contains one subelement. An AP should deliver frames to a non-AP STA within the time period specified in this attribute. Furthermore, when a non-AP STA requests admission control, the requested delay is only approved if it is equal to or greater than the value stored in the corresponding element. Each element is an unsigned integer that measures delay in units of microseconds.

The AP stores the information in the corresponding dot11NonAPStationAuthHCCAHEMMDelay elements of its MIB.

V.4.2.9 Authorized service access information

This parameter contains the relevant information for the AP to enforce the authorized service access type indicated in the Authorized Service Access Type element.
The Authorized Service Access parameters provide the VLAN assignment (VLAN ID and name) to which frames to or from the non-AP STA are bridged. The element includes VLAN ID (dot11NonAPStationVLANId) and VLAN Name (dot11NonAPStationVLANName).

**V.4.2.10 Non-AP STA transmission count**

This parameter indicates the count of the data traffic transmitted to and received from a non-AP STA. Such information would be used by the on-line charging and accounting function, especially for the IEEE 802.11 WLAN local service, where the data traffic does not necessarily go through the SSPN network. In such cases, Layer 3 accounting/charging information is not reliable since addresses could be spoofed. Layer 2 would be a better place to collect such information since due to the cryptographic security association that exists between the non-AP STA and AP.

The non-AP STA Transmission Count element includes information stored in the corresponding dot11NonAPStationVoiceMSDUCount, dot11NonAPStationVideoMSDUCount, dot11NonAPStationBestEffortMSDUCount, dot11NonAPStationBackgroundMSDUCount, dot11NonAPStationHCCAHEMMSDUCount, dot11NonAPStationMulticastMSDUCount, dot11NonAPStationVoiceOctetCount, dot11NonAPStationVideoOctetCount, dot11NonAPStationBestEffortOctetCount, dot11NonAPStationBackgroundOctetCount, dot11NonAPStationHCCAHEMMOctetCount, dot11NonAPStationMulticastOctetCount elements of the AP's MIB.

**V.4.2.11 Non-AP STA location information**

This parameter provides information about the STA's location to the SSPN. It is required by the SSPN applying location based service control. In the IEEE 802.11 network, the non-AP STA location is approximated using the AP’s location information. This includes two type of formats, Geospatial and Civic Location.

The information to be placed in the non-AP STA Location element is obtained from the dot11APGeospatialLocation and dot11APCivicLocation elements of the AP MIB.

**V.4.2.12 Non-AP STA State Information**

This parameter indicates whether non-AP STA is Active Mode or Power Saving. Information in this element is obtained from the corresponding dot11NonAPStationPowerManagementMode element of the associated AP MIB.

**V.5 Interworking with external networks and emergency call support**

**V.5.1 General**

Emergency services define the IEEE 802.11 functionality to support an emergency call (e.g., E911) service as part of an overall multi-layer solution, specifically capability advertisement and access to emergency services by STAs not having proper security credentials. “Multi-layer” indicates that emergency services will be provided by protocols developed in part by other standards bodies; see IETF ECRIT [B23], 3GPP TS 23.167 [B1], and 3GPP TS 22.067 [B3]. Three features of interworking with external networks support emergency call services.

The first feature is a mechanism for a non-AP STA to signal to an AP that a call is an emergency call. This is useful in the case where the access category to be used to carry the emergency call traffic (typically AC_VO) is configured for mandatory admission control. If the WLAN is congested, then the AP can deny the TSPEC
request for bandwidth to carry the call. However, if the AP is able to determine that the call is an emergency call, then it can invoke other options to admit the TSPEC request.

The second and third features provide the means for a client without proper security credentials to be able to place an emergency call. The second feature makes use of the Interworking element, which can be included in Association request frames in order to bypass the IEEE 802.1X port at an AP for unauthenticated access to emergency services. This is described further in V.5.5. The third feature makes use of an SSID configured for Open Authentication to provide emergency services and is described in V.5.3.

The STA has the burden to confirm the availability of emergency services from the IEEE 802.11 network, including that the network is authorized for emergency services. The time it takes for a client to find an authorized emergency services network is related to the speed of forward progress the authorized network can make over the air with the STA, relative to all of the other networks (attackers as well), and is inversely related to the number of false advertisements. A STA can confirm the availability of emergency services by observing the value of the Access Network Type, ESR and UESA fields in the Interworking element of any received Beacon or Probe response frame.

V.5.2 Background on emergency call support over IEEE 802.11 infrastructure

Special handling for emergency service calls is required over IEEE 802.11. To use a public hotspot a user will go typically through an authentication process (e.g., EAP-based, or http/https redirect or DNS redirection) before being able to use it for emergency calls.

There is a need to support these emergency services both when the user has a relationship with the IEEE 802.11 network (credentials to access the network) and when it does not have any relationship with the IEEE 802.11 network.

The former case requires no changes to the authentication process—the user, having already been authenticated to and associated with the WLAN, simply dials the emergency number thereby placing the call.

In the latter case, the non-AP STA will be able to gain access to the network without using security credentials and make an emergency call.

Another difficulty is that once the user gains access to the network, there is no mechanism to prioritize their emergency traffic in the IEEE 802.11 MAC over that of other users, even with IEEE 802.11 QoS capability.

Supporting emergency services, such as E911 calling, requires a multi-layer solution with support at various protocol layers. Apart from MAC level access and support for transfer of data between non-AP STA and AP with appropriate QoS at layer 2, there is a clear need, above this layer, to setup the call, conduct call control and management, and use an appropriate audio codec.

One specific example is when a user arrives in a new country and needs to make an emergency call in a public hotspot where there is no prior relationship with the available WLAN network or WLAN hotspot operator.

NOTE—The callback feature, if required in a regulatory domain, is dealt with at a higher layer.

V.5.3 System aspects for emergency call support

An IEEE 802.11 infrastructure by itself cannot ensure that all factors are compatible for an emergency service call to actually take place. The client device may have to register with a call manager (SIP agent or some other signaling endpoint) for the call to be placed successfully. Different signaling systems such as
SIP, H.323, etc., can be deployed for supporting emergency service calling. Higher layers can also verify an emergency service call is being placed so that appropriate level of resources can be granted to the emergency call. Voice endpoints (e.g., non-AP STAs) can use different codecs such as G.711, AMR, and iLBC. All these functionalities are outside the scope of this standard.

IEEE 802.11 can provide priority for emergency traffic both for the initial call establishment and during an ongoing emergency call, which assumes advertisement of this functionality supported in the BSS.

This subclause describes general design assumptions to support emergency services with IEEE 802.11:

a) It is assumed that there is a higher layer (above IEEE 802.11 Layer 2) protocol (or protocol suite) for making emergency calls or using any other emergency services.

b) In order to make the emergency call procedure work properly, the non-AP STA has the following responsibilities:

1) Recognize the user’s request to make an emergency call.
2) Select an AP that supports QoS and EBR capability.
3) Non-AP STA will associate with the AP if it is not already done so. In an RSN, if the user does not have valid authentication credentials for network access then non-AP STA can bypass the RSN that will provide access to the network to make emergency calls.
4) If location information is required in a particular regulatory domain, request location information from the WLAN. If the STA cannot determine its own location by its own means, then Location information should be obtained from the network prior to initiating the emergency call request. There are two methods a non-AP STA can use to obtain location services from the IEEE 802.11 network:

i) If the non-AP STA can use location information in Geospatial format (i.e., latitude, longitude and altitude), then the RM capability can be used to obtain this information. The AP advertises RM capability in its Beacon management frame (bit 1 set to 1 in the Capability information field). In this case, the non-AP STA transmits an LCI Request to the AP using the procedures in 10.11.9.6.

NOTE—The non-AP STA can receive an LCI Report with the incapable field set. According to the procedures in 10.11.9.6, the non-AP STA can resubmit an LCI Request with a location subject of “remote.” If the AP still responds with incapable, then location services are not available from the AP via RM capability.

ii) If the non-AP STA requires location information in Civic or Geospatial formats, then an AP’s wireless network management capability can be used. In this case, an AP advertises its ability to provide its location in with Civic or Geospatial format by setting the Civic Location or Geospatial Location field in the Extended Capabilities element to 1 in the Beacon frame. A non-AP STA requests its location using the procedures in 10.24.7. Unlike an AP providing RM capability, an AP Advertisement location capability will not return an “incapable” response if the non-AP STA requests the “remote” location.

5) Selects one of possibly several SSPNs advertising support for emergency services and VoIP service.

c) There are two methods described in this annex by which a user lacking security credentials can gain access to the network. The method selected in any particular deployment is at the discretion of the IEEE 802.11 infrastructure provider, SSPN or system administrator as appropriate. The AP and non-AP STA should permit users lacking security credentials to gain access to a network using one of two methods:

1) Using an emergency services association (see 8.4.2.94) in a BSS configured for RSNA. Using this type of association means the AP and non-AP STA will exchange unprotected frames for emergency service access only during the lifetime of the association. In this situation, cryptographic keys are not exchanged, the IEEE 802.1X uncontrolled port is bypassed without
invoking the IEEE 802.1X state machine. Since protection is used for authenticated STAs, their traffic is protected.

2) Using an SSID configured for Open System authentication. Network elements necessary to complete an emergency call are reachable via this SSID. How to reach these network elements (e.g., a call manager) and which protocol to use (e.g., SIP) are outside the scope of this standard.

d) The AP can separate the backhaul of emergency services traffic from other traffic, typically via a dedicated VLAN.

To ease burden of implementation on the network side, some basic means should exist to allow easy filtering, routing and basic access control of “regular” BSS traffic and emergency-type BSS traffic. This can be assisted by the downloading of emergency call number information, as described in 8.4.4.5.

**V.5.4 Description of the Expedited Bandwidth Request element**

For access categories configured for mandatory admission control, a non-AP STA requests bandwidth using a TSPEC element in an ADDTS Request frame. The TSPEC Request includes parameters describing the characteristics of the traffic stream, but no information on the use of the traffic stream. The Expedited Bandwidth Request (EBR) element describes the “use” of a traffic stream. To use this element, it is the responsibility of the station to transmit this element in response to certain call signaling messages. How this is done is outside the scope for the interworking service. The following bandwidth uses are provided in the EBR element:

- Emergency call, defined in NENA 08-002 [B52]
- Public first responder (e.g., fire department)
- Private first responder (e.g., enterprise security guard)
- Multi-level precedence and preemption (MLPP)

MLPP services are provided by other voice networking technologies such as 3GPP (see 3GPP TS 22.067 [B3]), H.323 (see ITU-T H4.60.14) and other proprietary signaling protocols. MLPP is used as a subscription service to provide differentiated levels of consumer service; it is also used by military organizations so that commanding officers will not get a network busy signal.

If the AP is provided additional information regarding the nature of the Traffic Stream, it can invoke additional policy that can be configured on the AP to accept the TSPEC request when it would be otherwise denied. Policy configured at AP defines how bandwidth is allocated. Specification of these policies is outside the scope of interworking with external networks. Policy examples include the following:

- No action
- Preemptive action: delete a TS of lower priority if necessary to make room for new TS
- Use capacity allocated for nonvoice services if priority is above a certain value (assuming TSPEC is for AC_VO)
- Interpret MLPP codes as defined 3GPP specification
- Interpret MLPP codes as defined in proprietary specification

**V.5.5 Access to emergency services in an RSN**

If an infrastructure BSS requires authentication and encryption with RSN, a non-AP STA placing an emergency call associates and authenticate to the network by using an emergency services association (see 8.4.2.94). If the non-AP STA has user credentials that allow it to use a particular network, the non-AP STA can use its credentials to authenticate to the SSPN through the IEEE 802.11 infrastructure.
When a mesh STA has an emergency services association, and it receives a Mesh Peering Open frame that includes the Interworking element, with ASRA bit equal to 1 and UESA bit equal to 0, and the Authenticated Mesh Peering Exchange element (see 8.4.2.120) it allows access to emergency services. If the mesh STA has user credentials that allow the accessing mesh STA to use the mesh network, the mesh STA can use its credentials to authenticate with the accessing mesh peer.

In order to use an emergency services association in an infrastructure BSS, a STA lacking security credentials can associate with a BSS in which emergency services are accessible by including an Interworking Element with the UESA field set to 1 in a (Re)Association Request frame. An AP receiving this type of (re)association request recognizes this as a request for unauthenticated emergency access. The AP can look up the VLAN ID to use with a AAA Server, or it can have an emergency services VLAN configured. The STA can either have, policies configured locally for quality-of-service parameters and network access restrictions, or it can look them up through external policy servers. When a mesh STA has an emergency services association, and it receives a Mesh Peering Open frame, from a mesh STA lacking security credentials, that includes the Interworking element, with ASRA bit equal to 1 and UESA bit equal to 1, and the Mesh Peering Management element (see 8.4.2.104) it allows access to emergency services.

When an emergency services association is used, an infrastructure BSS or an MBSS should be designed to restrict access to emergency services only (or alternatively prioritize the emergency services to the highest level of access). Methods of such restriction are beyond the scope of this standard, but can include an isolated VLAN for emergency services, filtering rules in the AP or network entity (e.g., router) in an external network to limit network access to only network elements involved in emergency calls, and per-session bandwidth control to place an upper limit on resource utilization.

V.6 Peer information

Peer information allows TDLS peer STAs to discover their capabilities. An example of peer information could be expressed in an XML format as follows:

```xml
<Peer information>
   <mode>tdls</mode>
   <wireless info>
      <mac address> 00:01:02:03:04:05 </mac address>
      <bssid> 00:0a:0b:0c:0d:0e </bssid>
   </wireless info>
   <network info>
      <DHCP>No</DHCP>
      <IP address>192.168.2.1</IP address>
      <Subnet>255.255.255.0</Subnet>
      <Hostname>myphone</Hostname>
   </network info>
</Peer information>
```

The minimum required peer information for TDLS is contained in “wireless info.” The “mac address” field contains the MAC address of the transmitting STA and the “bssid” identifies the BSS in which the STA is a member. The “network info” could optionally be used to aid the peer devices in establishing a TDLS link.
Annex W

(informative)

Mesh BSS operation

W.1 Clarification of Mesh Data frame format

The Mesh Data frame consists of MAC Header, Frame Body, and the FCS. The fields in the MAC Header are described in 8.2.3.

In a Mesh Data frame containing a single MSDU, the Mesh Control field is placed immediately before the Data (PDU) in the encrypted Frame Body. The Data (PDU) comprises the LLC/SNAP headers and the higher layer data. This is shown in the example frame format for a CCMP-encrypted Mesh Data frame containing a single MSDU in Figure W-1.

When the Mesh Data frame is fragmented, only the first fragment contains the Mesh Control field.

Figure W-1—Format of a CCMP-encrypted Mesh Data frame containing a single MSDU

W.2 Operational considerations for interworking

W.2.1 Formation and maintenance of the IEEE 802.1D spanning tree

No special action is required to support formation of the IEEE 802.1D spanning tree. Spanning tree control messages are typically delivered to bridges in group addressed frames. These messages are data frames from the point of view of the mesh BSS.

W.3 Power save parameters selection

W.3.1 General

Power save mechanisms enable mesh STA operation in Doze state. In Doze state a mesh STA may set the transceivers off. The power save mechanism may adjust the mesh power mode of a mesh STA for various reasons that are beyond the scope of the standard, including but not limited to traffic load or scanning and network maintenance needs.
This annex specifies recommendations on how a mesh STA selects mesh power modes based on traffic load, recommendations on how to do scanning in mesh BSSs that may contain mesh STAs in light or deep sleep mode, and recommended default values for power save related parameters.

W.3.2 Selecting the mesh power mode based on traffic load

A mesh STA may adjust its mesh power mode based on the traffic load or the QoS requirements of the forwarded traffic. If a mesh STA has high traffic load or if a mesh STA is congested, the mesh STA should operate in active mode on the corresponding mesh peering to reduce delays or overhead that may be created by the operation in light or deep sleep mode.

A mesh STA may consider staying in active mode for all peer mesh STAs, even if only a single link is congested. When mesh STA operates in active mode, the mesh STA may receive frames at any time and mesh peer service periods may be triggered on demand, as in case of an AP that receives a trigger frame at times controlled by a non-AP STA.

If traffic load is moderate or low and best effort data is transmitted, a mesh STA may consider staying in light sleep mode for all or some mesh peerings. The mesh STA in light sleep mode for a mesh peering receives beacons from the peer mesh STA with periodic indication of buffered traffic.

If traffic load is low or no traffic is transmitted, a mesh STA may consider staying in deep sleep mode for a mesh peering. The mesh STA does not need to wake up to receive a beacon from the peer mesh STA to which it is in deep sleep mode.

The mesh STA may use deep sleep mode to control the number of times it enters the Awake state to receive Beacon frame from a peer mesh STA. If the mesh STA is in deep sleep mode for all of its mesh peerings, the mesh STA needs only to remain in Awake state during its own beacon transmission and mesh awake window.

The mesh STA that forwards real time traffic (AC3 or AC2 with EDCA) should be in active mode for the corresponding link. A mesh STA forwarding real time traffic with EDCA may stay in light or deep sleep mode for the corresponding link, if the mesh STA is capable of initiating mesh peer service periods frequently and the other forwarding peer mesh STAs are in active mode. Poor handling of the mesh power modes may result to delays and inappropriate QoS of the forwarded MSDUs.

W.3.3 Scanning of mesh BSSs

A mesh BSS may have mesh STAs that alternate Awake state and Doze state. With active scanning only devices in Awake state at the transmission time of Probe Request frame may be found. However, with passive scanning also mesh STAs in light or deep sleep mode for a mesh peering can be found.

Since mesh STAs in light or deep sleep mode may transmit beacons at long intervals, a mesh STA seeking for candidate mesh STAs for a new mesh peerings should perform passive scanning relatively for a longer time compared to passive scanning in BSS infrastructure mode. Mesh STAs in light or deep sleep mode with long DTIM interval might not be discovered with short scanning durations. Mesh STAs that operate in light or deep sleep mode for a mesh peering may use a short DTIM interval, if they intend to establish new mesh peerings.

W.3.4 Default parameters

The following are the recommended default values for power save related parameters for mesh STAs:
Table W-1—Default parameters for mesh STAs that intend to operate in light or deep sleep mode for mesh peerings

<table>
<thead>
<tr>
<th></th>
<th>For moderate power save</th>
<th>For aggressive power save</th>
</tr>
</thead>
<tbody>
<tr>
<td>Beacon period</td>
<td>200 TU</td>
<td>800 TU</td>
</tr>
<tr>
<td>DTIM Period</td>
<td>4</td>
<td>1</td>
</tr>
<tr>
<td>Mesh awake window</td>
<td>10 TU</td>
<td>10 TU</td>
</tr>
</tbody>
</table>

A mesh STA that is eager to conserve power and likely to remain in deep sleep mode with most of the mesh peerings should utilize the value from aggressive power save parameters.

Although mesh STAs may utilize individual parameters regardless of the parameters used by neighbor mesh STAs or peer mesh STAs, each implementer should recognize balance between the power save efficiency and delay in the service initiation.

**W.3.5 MSDU forwarding in an MBSS containing mesh STAs in light or deep sleep mode**

The battery powered mesh STAs should avoid forwarding MSDUs, to avoid power consumption and possible additional delays and inefficiencies that power save mechanisms may cause. If a light or deep sleep mode mesh STA forwards MSDUs, it should select its mesh power mode based on the traffic load and the traffic type as described in W.3.2.

The mesh STAs that desire to save power may select the light or deep sleep mode for a mesh peering as follows:

- mesh STAs that are “mains powered” may apply light or deep sleep mode if they do not have MSDUs to forward
- mesh STAs that are “battery powered” and desire to minimize the power consumption may freely use all mesh power modes

Mesh STAs that are in light or deep sleep mode for a mesh peering may degrade the corresponding link metric value. The use of worse metric values reduces the probability of a link being used for MSDU forwarding. If the mesh STA will operate in active mode for the link in forwarding path, it should apply the link metric value without degradation.

**W.3.6 Synchronization maintenance of mesh STAs in deep sleep mode**

A mesh STA in deep sleep mode for a mesh peering might not receive Beacon frames from the corresponding peer mesh STA, but the mesh STA is required to maintain synchronization with the neighbor peer mesh STAs. Neighbor offset synchronization method imposes the maintenance of TSF offset values between neighbor peer mesh STAs, which generally requires the reception of Beacon frame or Probe Response frame. The simplest way to maintain the synchronization is that the mesh STA in deep sleep mode for a mesh peering listens to the corresponding peer mesh STA’s Beacon frame for certain periods and check the TSF offset value.

**W.4 SIV key wrapping test vector**

This test vector is from the appendix of IETF RFC 5297.

W.5 Airtime link metric usage example

The airtime cost constants (Table 13-4) and estimates of the average data rate and frame error rate will vary from one implementation and configuration of the IEEE 802.11 PHY and MAC to the other. While no mechanism is defined to measure the average data rate and the frame error rate, it is expected that numeric values will not exhibit large non-monotonic variations in amplitude over the lifetime of a path. Unstable measurements may cause path selection instabilities.

An example of an airtime link metric is provided to illustrate how it may be calculated.

Assume a DSSS PHY with an average data rate of 1 Mb/s to a given neighbor and a frame size of 8192 bits. The overhead O for the data frame is comprised of the PLCP preamble (144 μs) and the PLCP header (48 μs). The payload Bit is 8192 bits at an r of 1 Mb/s, or 8192 μs. The data transmission time is therefore 8416 μs. Other transmission times for different frame types are calculated in the same way (based on their size, rate, and overhead).

If RTS/CTS is used, the data transmission time (including PLCP preamble and header) is 8416 μs, the RTS transmission time (including PLCP preamble and header) is 352 μs, the CTS transmission time (including PLCP preamble and header) is 304 μs, the ACK transmission time (including PLCP preamble and header) is 304 μs and the interframe spacing overhead is 390 μs. The total time, including overhead, is 9766 μs.

This airtime and overhead value is converted to units of 0.01 TU (10.24 μs), i.e., 953.71 (rounded to 954).

If the frame error rate to the neighbor is 0%, the metric is 954. If the frame error rate is 80%, the metric is 4769 (i.e., 953.71/(1–0.8), rounded).

W.6 Generation of proactive PREPs in proactive PREQ mechanism of HWMP

W.6.1 General

In the proactive PREQ mechanism of HWMP, the generation of a proactive PREP in response to the receipt of a proactive PREQ depends on the value of the Proactive PREP subfield in the received proactive PREQ (see 13.10.4.2). Furthermore, if the Proactive PREP subfield is 0, the mesh STA may respond with the proactive PREP in case it needs a bidirectional path between the root mesh STA and itself. This is usually the case if the mesh STA has data to be sent to the root mesh STA. This clause provides a unified mechanism that controls the generation of proactive PREPs in the proactive PREQ mechanism of HWMP.

A proactive PREQ is defined by all of the following:

— The Target Address is set to all ones; and
— The TO subfield in the Per Target Flags field is 1.
W.6.2 Additions to forwarding information

The forwarding information to a root mesh STA contains two additional Boolean information fields. The Proactive PREP field indicates whether the mesh STA will generate a proactive PREP to the root mesh STA in response to a proactive PREQ (Proactive PREP = 1) or not (Proactive PREP = 0). The Proactive PREP Sent field indicates whether the mesh STA has sent a proactive PREP to the root mesh STA (Proactive PREP Sent = 1) or not (Proactive PREP Sent = 0). Both fields are initialized with 0.

W.6.3 Actions when sending data frames as source mesh STA

If a mesh STA receives proactive PREQs with the Proactive PREP subfield set to 0, the recipient mesh STA sends a proactive PREP before sending a data frame as source mesh STA only if the mesh STA has data to send to the root mesh STA, which requires establishing a bidirectional path with the root mesh STA and the field Proactive PREP Sent of the forwarding information to the root mesh STA is not set (=0).

If the mesh STA sends a data frame as source mesh STA to the root mesh STA, the mesh STA sets the field Proactive PREP of the forwarding information to 1.

W.6.4 Actions on receipt of proactive PREQ

If the mesh STA receives a proactive PREQ, the field Proactive PREP Sent of the forwarding information to the root mesh STA is set to 0. If the field Proactive PREP of the forwarding information to the root mesh STA is 1, the mesh STA generates a proactive PREP to the root mesh STA (see 13.10.10.3 Case D), sets the field Proactive PREP of the forwarding information to 0, and sets the field Proactive PREP Sent of the forwarding information to 1.

If the Proactive PREP subfield of the Flags field of the received proactive PREQ is 1, the mesh STA sets the field Proactive PREP of the forwarding information to the root mesh STA to 1.

W.6.5 Generation of proactive PREPs

A mesh STA will generate a proactive PREP according to 13.10.10.3 Case D if one of the following applies:

- [The mesh STA has received a proactive PREQ] AND [in the forwarding information to the root mesh STA of the proactive PREQ, field Proactive PREP is set to 1 AND field Proactive PREP Sent is set to 0].
- [The mesh STA has data to send to the root mesh STA, which requires establishing a bidirectional path with the root mesh STA] AND [the field Proactive PREP Sent of the forwarding information to the root mesh STA is not set (=0)].

If the mesh STA generates a proactive PREP to the root mesh STA, the field Proactive PREP Sent of the forwarding information is set to 1 and the field Proactive PREP of the forwarding information is set to 0.
W.7 Generation of PREQs in proactive RANN mechanism of HWMP

W.7.1 General

In the proactive RANN mechanism of HWMP, the generation of a PREQ for root path confirmation in response to the receipt of a RANN depends on the path metric from the mesh STA to the root mesh STA as computed by the RANN propagation. However, the RANN mechanism does not setup the necessary forwarding information. This is done with individually addressed PREQs. This clause provides further details to the generation of individually addressed PREQs in the proactive RANN mechanism of HWMP.

An individually addressed PREQ is defined by the following:

— The Addressing Mode subfield in the Flags field is 1 (individually addressed).

W.7.2 Additions to forwarding information

The forwarding information to a root mesh STA contains an additional address field. The RANN Sender Address field contains the MAC address of the neighbor peer mesh STA that has sent the RANN with the best metric.

W.7.3 Actions when sending data frames as source mesh STA

If the mesh STA sends a data frame as source mesh STA to the root mesh STA, the mesh STA uses the forwarding information to the root mesh STA. The RANN Sender Address is not used for forwarding Mesh Data frames to the root mesh STA.

W.7.4 Actions on receipt of proactive RANN

If the mesh STA receives a proactive RANN, the field RANN Sender Address of the forwarding information to the root mesh STA is set to the sender of the RANN element if the metric to the root mesh STA is better than the path metric of the existing mesh path in the forwarding information.

In this case, the mesh STA generates an individually addressed PREQ to the root mesh STA—see 13.10.10.3 Case D (Root Path Confirmation (Original Transmission)). This individually addressed PREQ is not sent according to the general forwarding information. Instead, it is sent to the neighbor peer mesh STA indicated in the RANN Sender Address field.

Since all mesh STAs between the mesh STA and the root mesh STA have already a value in the RANN Sender Address field, the individually address PREQ will eventually reach the root mesh STA. Since the TO subfield in the Per Target Flags field is 1, only the root mesh STA will generate a PREQ as reply to the individually addressed PREQ.

The individually addressed PREQs will setup forwarding information (that can be used for forwarding Mesh Data frames) from the root mesh STA towards the mesh STA that initiated the root path confirmation in all intermediate mesh STAs according to the normal HWMP procedures.

Note, since the PREQ is sent in an individually addressed frame, every sender of the individually addressed PREQ will be able to determine whether the next mesh STA towards the root mesh STA has received the PREQ.

The root mesh STA will generate a PREP according to the normal HWMP procedures—see 13.10.10.3 Case A (Original Transmission).
W.7.5 Actions on receipt of PREP

The PREP generated by the root mesh STA will be forwarded on the mesh path from the root mesh STA to the mesh STA as setup by the individually addressed PREQ. The PREP will be propagated and will eventually reach the mesh STA. The PREP will setup forwarding information (that can be used for forwarding Mesh Data frames) towards the root mesh STA in the mesh STA that initiated the root path confirmation and in all intermediate mesh STAs on this path according to the normal HWMP procedures.

After establishing the forwarding information (mesh path) towards the root mesh STA, the path to the root mesh STA is updated to the better one.

Note that since the PREP is sent in an individually addressed frame, every sender of the PREP will be able to determine whether the next mesh STA has received the PREP.
